#### Abstract

For a $\wedge$-semidistributive lattice $L$, we study some particular implicational systems and show that the cardinality of a minimum implicational basis is polynomial in the size of join-irreducible elements of the lattice $L$. We also provide a polynomial time algorithm to compute a minimum implicational basis for $L$. © 2006 Published by Elsevier B.V. Keywords: Algorithms; Lattice; Closure system; Minimum implicational basis

## 1. Introduction

This paper deals with the computation of a minimum implicational basis for a closure system. Computing a minimum implicational basis for a lattice given by its poset of irreducible elements is an important problem, which has applications to many areas of computer science, in particular to databases and AI [1,4,6,7,10]. For a survey on this problem and related areas, see [3].

The complexity of this problem remains open for general lattices. Recent progress on the status of this problem, and in particular solvability by limited nondeterminism [5], suggests however that this problem is more likely to be expected tractable than intractable [4].

It has been already shown that this problem is tractable for the two classes of locally distributive lattice [2] and of modular lattices [14]. In this paper we

[^0]show by using a dependence relation in [11] that the class of $\wedge$-semidistributive lattices is another tractable case.

Consider a finite set $U$. A subset $\mathcal{C} \subseteq 2^{U}$ is said to be a closure system if $\mathcal{C}$ is closed under set-intersection and containing the set $U$. An implication on $U$ is an ordered pair $(A, B)$ of subsets of $U$, denoted by $A \rightarrow B$. The set $A$ is called the premise and the set $B$ the conclusion of the implication $A \rightarrow B$. Let $\Sigma$ be a set of implications on $U$. A subset $D \subseteq U$ is $\Sigma$-closed if for each implication $A \rightarrow B$ in $\Sigma, A \subseteq D$ implies $B \subseteq D$. The set of $\Sigma$-closed subsets of $U$, denoted by $\mathcal{C}(\Sigma)$, is a closure system on $U$. Conversely, given a closure system $\mathcal{C}$ on $U$, a family $\Sigma$ of implications on $U$ is said an implicational basis for $\mathcal{C}$ if $\mathcal{C}=\mathcal{C}(\Sigma)$. An implicational basis is said minimum if it has a minimum number of implications.

In this paper, we study the latticial version of this problem. We view a lattice $L$ as the closure system $\mathcal{C}_{L}$ on the set $J(L)$ of its join-irreducible elements. More precisely, put $J(a)=\{j \in J(L): j \leqslant a\}$ for $a \in L$.

Fig. 1. (a) A lattice $L$ where join-irreducible (resp. meet-irreducible) elements are labeled by letters (resp. numbers); (b) The closure system $c l$ associated to $L$.

Then $\mathcal{C}_{L}=\{J(a): a \in L\}$ is a closure system on $J(L)$ which, as a lattice ordered by inclusion, is isomorphic to $L$.

Fig. 1 gives an example of the closure system $\mathcal{C}_{L}$ associated to a lattice $L$.

The closure system $\mathcal{C}_{L}$ can be defined by the set of its meet-irreducible elements $\mathcal{M}\left(\mathcal{C}_{L}\right)=\{J(m): m \in$ $M(L)\}$, where $M(L)$ denotes the set of meet-irreducible elements of $L$. Each element of $\mathcal{C}_{L}$ can be obtained as intersection of some elements of $\mathcal{M}\left(\mathcal{C}_{L}\right)$.

The problem we study is:
Problem: Minimum implicational basis
Instance: The set of meet-irreducible elements $\mathcal{M}\left(\mathcal{C}_{L}\right)$ of the closure system $\mathcal{C}_{L}$.
Question: Find a minimum basis $\Sigma$ for $\mathcal{C}_{L}$.
This problem remains open for general lattices. Duquenne [2] has given a latticial version of this problem and shown that it is polynomial for upper locally distributive lattices or antimatroid. Recently, Wild [14] has proposed a polynomial time algorithm to compute an optimal ${ }^{1}$ implicational basis for modular lattices. In the following, we study the case of $\wedge$-semidistributive lattices. For such lattices we show that the number of implications of a minimum implicational basis is at most $|J(L)|^{2}$ and give a polynomial time algorithm to compute such a basis.

## 2. Some properties of $\wedge$-semidistributive lattices

Let $L$ be a finite lattice. We note $\vee$ the join operation, $\wedge$ the meet operation and $\prec$ the cover relation of $L$. If $j$ is a join-irreducible element of $L$, we use $j_{*}$ to denote

[^1]the unique element covered by $j$. Dually, we use $m^{*}$ to denote the unique element covering a meet-irreducible element $m$.

We will use the arrow relations introduced by Wille [15]: for $x, y \in L, x \downarrow y$ means that $x$ is a minimal element of $\{z \in L: z \nless x\}, x \uparrow y$ means that $y$ is a maximal element of $\{z \in L: z \ngtr y\}$ and $x \uparrow y$ means that $x \uparrow y$ and $x \downarrow y$. Recall that $\uparrow, \downarrow, \downarrow$ are relations defined on $J(L) \times M(L)$, where $J(L)$ is the set of join-irreducible elements and $M(L)$ the set of meet-irreducible elements of $L$.

In the following, we deal essentially with $\wedge$-semidistributive lattices. Let us recall that a lattice $L$ is said $\wedge$-semidistributive if for all elements $x, y, z \in L, x \wedge$ $y=x \wedge z$ implies $x \wedge y=x \wedge(y \vee z)$. A $\wedge$-semidistributive lattice is said semidistributive if for all elements $x, y, z, x \vee y=x \vee z$ implies $x \vee y=x \vee(y \wedge z)$. The following characterization of these lattices are well known (see, for example, [6]):

Property 1. A finite lattice $L$ is $\wedge$-semidistributive if and only if for any $j \in J(L)$ there exists a unique $m \in$ $M(L)$ such that $j \downarrow m$.

For any $\wedge$-semidistributive lattice $L$ and $j \in J(L)$, we denote by $m(j)$ the unique element $m \in M(L)$ such that $j \downarrow m$.

We define the mapping $\gamma: J(L) \rightarrow 2^{M(L)}$ by $\gamma(j)=$ $\{m \in M(L): j \downarrow m\}$. This mapping was introduced in [12] to define colored posets, which provides a new representation for lattices, and specially for upper locally distributive lattices. Fig. 2 shows the $\gamma$ mapping of the lattice of Fig. 1. Note that this lattice is semidistributive.

We consider one of the standard dependence relations defined on join-irreducible elements (assuming

that the lattice $L$ is $\wedge$-semidistributive) as follows (see, for example, $[8,11])$ :

Let $j, j^{\prime} \in J(L)$.
Then $j B j^{\prime} \quad$ iff $\quad j \neq j^{\prime}, j^{\prime} \nless m(j), j_{*}^{\prime} \leqslant m(j)$.
For an illustration of that definition, see Fig. 3.
There are relationships between the existence of cycles in the graph of the relation $B$ and some classes of lattices. For example, Nation has shown that a $\wedge$-semidistributive lattice is semidistributive if and only if it contains no $B$-cycle of length 2 [11].

The following lemma gives a rewriting of the definition of the relation $B$ using the mapping $\gamma$.

Lemma 1. Let L be a $\wedge$-semidistributive lattice, $j, j^{\prime} \in$ $J(L)$.
$j B j^{\prime} \quad$ iff $\quad j \neq j^{\prime}$ and $m(j) \in \gamma\left(j^{\prime}\right)$.

## 3. Minimum implicational basis for $\wedge$-semidistributive lattices

In this section, we give a polynomial time algorithm to compute a minimum implicational basis for a $\wedge$-semidistributive lattice.

We start with two technical lemmas on closed sets of a closure system $\mathcal{C}_{L}$. The first one is obvious since the elements of $\mathcal{C}_{L}$ are order ideals of the induced poset by $J(L)$.

Lemma 2. Let $j, j^{\prime} \in J(L)$ such that $j<j^{\prime}$ and $X \in$ $\mathcal{C}_{L}$. Then $j^{\prime} \in X$ implies $j \in X$.

Consider now a $\wedge$-semidistributive lattice $L$ and $j, j^{\prime} \in J(L)$ such that $j B j^{\prime}$. We denote by $P_{j j^{\prime}}$ the set $J\left(j_{*}\right) \cup J\left(j^{\prime}\right)$.

Lemma 3. Let $L$ be a $\wedge$-semidistributive lattice and $j, j^{\prime} \in J(L)$ such that $j B j^{\prime}$ and $X \in \mathcal{C}_{L}$. Then $P_{j j^{\prime}} \subseteq X$ implies $j \in X$.

Proof. Let $x \in L$ such that $X=J(x)$ and $P_{j j^{\prime}} \subseteq X$. Since $J\left(j_{*}\right) \subset X$ this implies that $j_{*} \vee j^{\prime} \leqslant x$, and then it suffices to prove that $j \leqslant j_{*} \vee j^{\prime}$.

Suppose that $j \not j_{*} \vee j^{\prime}$ and let $m^{\prime} \in M(L)$ be a maximal element of $\left\{z \in L \mid z \ngtr j\right.$ and $\left.z \geqslant j_{*} \vee j^{\prime}\right\}$. By definition of $m^{\prime}$, we have $j \uparrow m^{\prime}$. Moreover $j \downarrow m^{\prime}$ since $j_{*} \leqslant m^{\prime}$. Thus $j \rightsquigarrow m^{\prime}$.

Consider now the meet-irreducible $m(j)$ associated with $j$. Then $j^{\prime} \nless m(j)$ since $j B j^{\prime}$. Thus since $j^{\prime} \leqslant m^{\prime}, m^{\prime}$ and $m(j)$ are two distinct elements such that $j \downarrow m^{\prime}$ and $j \downarrow m(j)$. This contradicts the fact that $L$ is $\wedge$-semidistributive.

We can now define a particular set of implications associated to a $\wedge$-semidistributive lattice $L$. Let $\Sigma_{1}=$ $\{j \rightarrow J(j)\}, \Sigma_{2}=\left\{P_{j j^{\prime}} \rightarrow j \mid j^{\prime} \in J(L)\right.$ and $\left.j B j^{\prime}\right\}$ and $\Sigma=\Sigma_{1} \cup \Sigma_{2}$.

For example, the sets of implications $\Sigma_{1}$ and $\Sigma_{2}$ for the lattice in Fig. 1 are $\Sigma_{1}=\{b \rightarrow a b, d \rightarrow c d, e \rightarrow$ $c d e, f \rightarrow c d e f, g \rightarrow c d g\}$ and $\Sigma_{2}=\{a c d \rightarrow e, a b c \rightarrow$ $d$, acdef $\rightarrow b$, acd $g \rightarrow b, c d e g \rightarrow f\}$.

The following theorem shows that $\Sigma$ is an implicational basis for $\mathcal{C}_{L}$.

Theorem 1. Let $L$ be a $\wedge$-semidistributive lattice. Then the set of implications $\Sigma$ is an implicational basis for $\mathcal{C}_{L}$.

Proof. We need to show that $\mathcal{C}_{\Sigma}=\mathcal{C}_{L}$.
Let $X \in \mathcal{C}_{L}$. By Lemma $2, X$ is $\Sigma_{1}$-closed. By Lemma 3, $X$ is $\Sigma_{2}$-closed. Then $X$ is $\Sigma$-closed and $\mathcal{C}_{L} \subseteq \mathcal{C}_{\Sigma}$.

Now let us show that $\mathcal{C}_{\Sigma} \subseteq \mathcal{C}_{L}$. Let $X \in \mathcal{C}_{\Sigma}$. Let $x_{0}=\bigvee X$, i.e., the least closed set containing $X$. Clearly $X$ is an ideal since it is $\Sigma_{1}$-closed. Suppose that $X \notin \mathcal{C}_{L}$ and let $j$ be a minimal element of $J\left(x_{0}\right) \backslash X$. Since $j \leqslant$ $x_{0}$, we have $x_{0} \nless m(j)$. Moreover $X \nsubseteq J(m(j))$, otherwise one would have $\bigvee X \leqslant m(j)$ and then $\bigvee X \neq x_{0}$. Thus there exists an element $j^{\prime} \in X$ such that $m(j) \in$ $\gamma\left(j^{\prime}\right)$ and therefore $P_{j j^{\prime}} \rightarrow j \in \Sigma$ with $P_{j j^{\prime}} \subseteq X$ and $j \notin X$. Then $X$ is not $\Sigma$-closed, which concludes the proof.

Corollary 1. Let $L$ be $a \wedge$-semidistributive lattice. Then there exists an implicational basis for $\mathcal{C}_{L}$ with at most $|B|+|J(L)|$ implications, where $|B|$ is the number of arcs in the relation $B$.

```
Data: Let \(L\) be a \(\wedge\)-semidistributive lattice and \(\mathcal{M}\left(C_{L}\right)\) the set of meet-irreducible elements of \(\mathcal{C}_{L}\).

\(\Sigma=\emptyset ;\)
for \(j \in J(L)\) do
\[
\Sigma=\Sigma \cup\{j \rightarrow \varphi(j)\}
\]
for \(j^{\prime} \in J(L)\) do \(P=(\varphi(j)) \backslash\{j\} \cup \varphi\left(j^{\prime}\right) ;\) \(\Sigma=\Sigma \cup\{P \rightarrow(P)\} ;\)
\(\Sigma=\) a nonredundant cover of \(\Sigma ;\)
end
```

$$
\text { Algorithm 1. Minimum- } \operatorname{Basis}\left(\mathcal{M}\left(C_{L}\right)\right)
$$

Clearly the set $\Sigma$ of implications obtained as above is in general not minimum. For instance, for the set $\Sigma$ associated to the lattice in Fig. 1, the implication $a c d g \rightarrow b$ is redundant ${ }^{2}$ and can be removed from $\Sigma$ without changing $\mathcal{C}(\Sigma)$.

In the following we give a polynomial time algorithm to compute a minimum basis for a $\wedge$-semidistributive lattice.

### 3.1. Algorithm

This is based on Theorem 1 and the algorithm in [13]. Indeed, the algorithm in [13] computes a minimum basis (called there a minimum cover) from any given basis in polynomial time.

Let $\mathcal{M}\left(\mathcal{C}_{L}\right)$ be the set of meet-irreducible elements. Consider the closure operator $\varphi: 2^{J} \rightarrow 2^{J}$, with for $X \subseteq$ $J, \varphi(X)=\bigcap\left\{M \in \mathcal{M}\left(\mathcal{C}_{L}\right) \mid X \subseteq M\right\}$. The images of the mapping $\varphi$ are said closed sets, and they correspond to the elements of the closure system $\mathcal{C}_{L}$.

Remark 1. We replaced $P \rightarrow j$ by $P \rightarrow \varphi(P)$ to guarantee the minimality after the calculation of a nonredundant cover of $\Sigma$.

Remark 2. Let us note that Algorithm 1 does not compute the same $\Sigma$ as that of Theorem 1. This to avoid the computation of the relation $B$. But like the whole of the implications calculated by Algorithm 1 contains all implications of Theorem 1 (relative with the preceding remark), this guaranteed to us to have a cover of $\mathcal{C}_{L}$.

Theorem 2. Let L be a $\wedge$-semidistributive lattice. Then Algorithm 1 computes a minimum implicational basis $\Sigma$

[^2]of $\mathcal{C}_{L}$ in $\mathrm{O}\left(|J|^{5}+|J|^{3}\left|\mathcal{M}\left(\mathcal{C}_{L}\right)\right|\right)$ time complexity. Moreover, the size of $\Sigma$ is at most $|J(L)|^{2}$ implications.

Proof. Theorem 1 guarantees that $\Sigma$ is a basis for the closure system $\mathcal{C}_{L}$. Since the conclusions of all implications are closed by the mapping $\varphi$, the result in [13] guarantees that a not redundant basis is minimum.

Computing the closure of a set $X \subseteq J(L)$ by $\varphi$ can be done in $\mathrm{O}\left(\left|J(L) \| \mathcal{M}\left(\mathcal{C}_{L}\right)\right|\right)$ time complexity. Thus the total time complexity for computing a basis is in $\mathrm{O}\left(|J(L)|^{3}\left|\mathcal{M}\left(\mathcal{C}_{L}\right)\right|\right)$. Now computing a not redundant basis can be done in $\mathrm{O}\left(|J(L)||\Sigma|^{2}\right)$. Since $\Sigma$ has at most $|J(L)|^{2}$ implications, we conclude that the time complexity of Algorithm 1 is in $\mathrm{O}\left(|J(L)|^{5}+\right.$ $\left.|J(L)|^{3}\left|\mathcal{M}\left(\mathcal{C}_{L}\right)\right|\right)$.
