#### Abstract

Given a ground set $L$ of labels and a collection of trees whose leaves are bijectively labelled by some elements of $L$, the Maximum Agreement Supertree problem (SMAST) is the following: find a tree $T$ on a largest label set $L^{\prime} \subseteq L$ that homeomorphically contains every input tree restricted to $L^{\prime}$. The problem finds applications in phylogenetics, databases and data mining. In this paper we focus on the parameterized complexity of this NP-hard problem. We consider different combinations of parameters for SMAST as well as particular cases, providing both FPT algorithms and intractability results.

## 1 Introduction

Motivation. Supertree construction consists in building trees on a large set of labels from smaller trees covering parts of the label set. This task finds application in bioinformatics where trees represent phylogenies, but also in other fields [1, 2]. In phylogenetics, the labels are bijectively associated with the leaves of the trees and represent current organisms, while internal nodes represent hypothetical ancestors. The topological information in the input trees consists in the groupings of labels induced by internal nodes, representing related sets of organisms such as species, orders, families, etc. The goal is to build a supertree complying as much as possible with the topological information of the source trees. The task is relatively easy when the input trees agree on the relative positions of the labels. In this case, it is possible to find in polynomial time a supertree that contains any input tree as an induced subtree, hence that incorporates all topological information provided by the data [1]. However, in practice several input trees usually disagree on the position of some leaves with respect to other leaves.

Related work. Some methods aim at producing supertrees incorporating as much input information as possible under the constraint that they do not contradict any input tree: they avoid disagreements between the input trees by collapsing some of their edges [3, 4] or by excluding some of their leaves, i.e. labels. The Maximum Agreement Supertree (SMAST) method [5-7] is apparented to the latter kind. Given a collection $\mathcal{T}$ of $k$

[^0]trees of maximum degree $d$ with labels taken in a ground set $L$ of size $n$, an agreement supertree for $\mathcal{T}$ is a tree $T$ on a subset $L^{\prime} \subseteq L$ such that each tree of $\mathcal{T}$ restricted to $L^{\prime}$ is included in $T$. The SMAST problem consists in finding an agreement supertree containing the maximum number of labels from $L$.

This problem is NP-hard in general as it generalizes the MAST problem [8]. SMAST remains NP-hard when $d$ is unrestricted for $k \geq 3$ input trees [6] and for trees of degree $d \geq 2$ when $k$ is unrestricted [5]. Moreover, [6,5] have also considered the complement problem, which is a minimization problem where the measure is the number $p$ of labels missing in an agreement supertree. This problem can not be approximated in polynomial time within a constant factor, unless $\mathrm{P}=\mathrm{NP}$ [5]. The corresponding decision problem parameterized in $p$ is $\mathrm{W}[2]$-hard [5].

For the particular case of $d=2$, [6] gave an $O\left(n^{k^{2}}\right)$ algorithm for SMAST. For $k=2$ both $[6,5]$ shown that SMAST can be solved in polynomial time, by reduction to MAST.

Our results. In this paper, we focus on the particular case where $d=2$. Note that in phylogenetics, the input trees of SMAST will often be binary as a result of the optimization algorithms used to analyze raw molecular data. We improve on previous results in several ways.

First, we show that SMAST on $k$ rooted binary trees on a label set of size $n$ can be solved in $O\left((2 k)^{p} k n^{2}\right)$. This algorithm is only exponential in $p$, that roughly represents the extent to which the input trees disagree. Thus, the algorithm will be reasonably fast when dealing with collections of trees obtained for genes displaying a low level of homoplasy. Then, we provide an $O\left((8 n)^{k}\right)$ algorithm, independent of $p$, and significantly improving on the $O\left(n^{k^{2}}\right)$ algorithm of [6]. This algorithm shows that SMAST is tractable for a small number of trees, extending in some sense the previously known results for $k=2$ trees $[6,5,9]$. We also obtain some fixed-parameter intractability results for various combinations of parameters of SMAST.

We then consider SMAST on collections of rooted triples (binary trees on 3 leaves), focusing on the complexity of this variant parameterized in $p$. Since this problem is equivalent to SMAST in its general setting [9], it is W[2]-hard. However, we show here that an FPT algorithm can be achieved for complete collections of rooted triples, i.e., when there is at least one rooted triple for each set of 3 labels in $L$. This results from the fact that conflicts between the input trees can be circumvented to small sets of labels, leading to $O\left(4^{p} n^{3}\right)$ and $O\left(3.12^{p}+n^{4}\right)$ algorithms.

## 2 Definitions

We consider rooted trees which are bijectively leaf-labelled. Let $T$ be such a tree, we identify its leaf set with its label set, denoted by $L(T)$. The size of $T$ is $|T|:=|L(T)|$.

The node set of $T$ is denoted by $N(T)$, and $r(T)$ stands for the root of $T$. We use a parenthesized notation for trees: if $x$ is a label, then $x$ denotes the tree whose root is a leaf labelled by $x$; if $T_{1}, \ldots, T_{k}$ are trees, then $\left(T_{1}, \ldots, T_{k}\right)$ stands for the tree whose root is connected to the child subtrees $T_{1}, \ldots, T_{k}$.

If $x$ is a node of $T, T(x)$ stands for the subtree of $T$ rooted at $x$, and $L(x)$ for the label set of this subtree. If $x, y$ are two nodes of $T$, then $x<_{T} y$ means that $x$ is a descendant of $y$ in $T$. The upper bound of two nodes $x, y$ of $T$ w.r.t. $<_{T}$ is called the lowest common ancestor of $x, y$, and is denoted by $\operatorname{lca}_{T}(x, y)$. If $x, y$ are two nodes of $T$ s.t. $x<_{T} y$, denote by $\operatorname{child}_{T}(x, y)$ the child of $y$ along the path joining $y$ to $x$ in $T$. If $x$ is an internal node of $T$, the set of children of $x$ in $T$ is denoted by children ${ }_{T}(x)$.

Given a tree $T$ and a label set $L$, the restriction of $T$ to $L$, denoted by $T \mid L$, is the tree homeomorphic to the smallest subtree of $T$ connecting leaves of $L$. Let $T, T^{\prime}$ be two trees. We say that $T$ embeds in $T^{\prime}$, denoted by $T \leq T^{\prime}$, iff $T=T^{\prime} \mid L(T)$. We say that $T$ partially embeds in $T^{\prime}$, denoted by $T \bowtie T^{\prime}$, iff $T\left|L\left(T^{\prime}\right)=T^{\prime}\right| L(T)$. A collection is a family $\mathcal{T}=\left\{T_{1}, \ldots, T_{k}\right\}$ of trees, the label set of the collection is $L(\mathcal{T})=\cup_{i=1}^{k} L\left(T_{i}\right)$. Given a label set $L$, the restriction of $\mathcal{T}$ to $L$ is the collection $\mathcal{T} \mid L=\left\{T_{1}\left|L, \ldots, T_{k}\right| L\right\}$. See Figure 1 for an example of a collection.

Fig. 1. A collection $\mathcal{T}$ of 3 input trees.

An agreement supertree for $\mathcal{T}$ is a tree $S$ s.t. $L(S) \subseteq L(\mathcal{T})$ and for each $i \in[k], S \bowtie T_{i}$. We say that $S$ is a total agreement supertree for $\mathcal{T}$ if additionnally $L(S)=L(\mathcal{T})$. The collection $\mathcal{T}$ is compatible iff there exists a total agreement supertree for $\mathcal{T}$. A conflict between $\mathcal{T}$ is a set $C \subseteq L(\mathcal{T})$ s.t. $\mathcal{T} \mid C$ is incompatible. For instance, $T=(((a, b), c),(e, f))$ is an agreement supertree for the collection $\mathcal{T}$ of Figure 1, and $C=\{a, b, c, d\}$ is a conflict between $\mathcal{T}$.

Given a collection $\mathcal{T}$, we define $S M A S T(\mathcal{T})$ as the set of agreement supertrees for $\mathcal{T}$. The Maximum Agreement Supertree problem (Smast) asks: given a collection $\mathcal{T}$, find an agreement supertree for $\mathcal{T}$ with the largest size. Equivalently, it amounts to seek a largest set $L \subseteq L(\mathcal{T})$ s.t. $\mathcal{T} \mid L$ is compatible. The size of such an optimal solution is denoted by $\# S M A S T(\mathcal{T})$. We also denote by P-SmAst the parameterized version of SmAst, which asks: given a collection $\mathcal{T}$ and a parameter $p$, can $\mathcal{T}$ be made compatible by removing at most $p$ labels?

## 3 Solving Smast on binary trees

Throughout this section, we consider a fixed collection $\mathcal{T}=\left\{T_{1}, \ldots, T_{k}\right\}$ of binary trees, we let $n$ denote the size of the label set and $k$ the number of trees.

If $T$ is a tree, we define $N^{\perp}(T):=N(T) \cup\{\perp\}$. We extend the notation $T(u)$ to $u \in N^{\perp}(T)$, s.t. if $u=\perp$ then $T(u)$ is the empty tree. We extend the relation $\leq_{T}$ to $N^{\perp}(T)$ s.t. $\perp \leq_{T} x$ for each $x \in N^{\perp}(T)$.

A position in $\mathcal{T}$ is a tuple $\pi=\left(u_{1}, \ldots, u_{k}\right)$, where each $u_{i} \in N^{\perp}\left(T_{i}\right)$. For $i \in[k]$, the $i$ th component of $\pi$ is denoted $\pi[i]$. We set $I(\pi)=\left\{i \in[k]: \pi[i]\right.$ is an internal node of $\left.T_{i}\right\}$. We define the initial position $\pi_{\top}=\left(r_{1}, \ldots, r_{k}\right)$, where each $r_{i}$ is the root of $T_{i}$. We define the final position $\pi_{\perp}=(\perp, \ldots, \perp)$. We let $\Pi(\mathcal{T})$ denote the set of positions in $\mathcal{T}$.

### 3.1 Solving Smast in $O\left((2 k)^{p} \times k n^{2}\right)$ time

In this section, we describe an algorithm deciding the compatibility of a collection in $O\left(k n^{2}\right)$ time, and returning a conflict of size $\leq 2 k$ in case of incompatibility. This yields an FPT algorithm for P-Smast with $O\left((2 k)^{p} \times k n^{2}\right)$ running time.

The well-known Build algorithm $[1,10]$ decides the compatibility of a collection but doesn't give a conflict in case of incompatibility. Like Build, the algorithm presented here builds the supertree using a recursive top-down approach. Each step constructs a graph where the connected components correspond to the subtrees hanging from the root of the supertree. However, we replace the graph used in Build with a graph that when connected yields a conflict of size $\leq 2 k$, identified thanks to a spanning tree.

We begin with some additional definitions. A position is reduced iff each component is either $\perp$ or an internal node; to any position $\pi$, we associate a reduced position $\pi \downarrow$ by replacing by $\perp$ any component of $\pi$ that is a leaf. In the following, we will assume that $\pi$ is a reduced position in $\mathcal{T}$. We set $\mathcal{T}(\pi):=\left\{T_{1}\left(u_{1}\right), \ldots, T_{k}\left(u_{k}\right)\right\}$.

We define the graph $G(\mathcal{T}, \pi)$ as follows: (i) its vertex set is $V=\cup_{i \in I(\pi)}$ children $_{T_{i}}(\pi[i])$; (ii) two vertices $x, y \in V$ are adjacent iff $L(x) \cap L(y) \neq \emptyset$. In other terms, $G(\mathcal{T}, \pi)$ is the intersection graph of the set system $\{L(x): x \in V\}$. See Figure 2 for an example of such graphs.
If $V^{\prime} \subseteq V$, we define the position $\operatorname{Succ}_{V^{\prime}}(\pi)$ as the position $\pi^{\prime}$ s.t.

- if $\pi[i]=\perp$, then $\pi^{\prime}[i]=\perp$;
- if $\pi[i]$ is an internal node of $T_{i}$, with children $v_{i}, v_{i}^{\prime}$, then one of the following holds: (i) $\pi^{\prime}[i]=v_{i}$ if $v_{i} \in V^{\prime}, v_{i}^{\prime} \notin V^{\prime}$, (ii) $\pi^{\prime}[i]=v_{i}^{\prime}$ if $v_{i} \notin V^{\prime}, v_{i}^{\prime} \in V^{\prime}$, (iii) $\pi^{\prime}[i]=u_{i}$ if $v_{i} \in$ $V^{\prime}, v_{i}^{\prime} \in V^{\prime}$, (iv) $\pi^{\prime}[i]=\perp$ if $v_{i} \notin V^{\prime}, v_{i}^{\prime} \notin V^{\prime}$.
We set $\operatorname{succ}_{V^{\prime}}(\pi)=\operatorname{Succ}_{V^{\prime}}(\pi) \downarrow$. Given $V^{\prime} \subseteq V$, set $L\left(V^{\prime}\right)=\cup_{x \in V^{\prime}} L(x)$. Set $L(\pi)=$ $L(\mathcal{T}(\pi))$. We will repeatedly use the following simple observations:

Lemma 1. Let $V^{\prime} \subseteq V$. Then: $L\left(\operatorname{Succ}_{V^{\prime}}(\pi)\right) \subseteq L\left(V^{\prime}\right)$.
Lemma 2. Two sets $V_{1}, V_{2} \subseteq V$ are connected in $G(\mathcal{T}, \pi)$ iff $L\left(V_{1}\right) \cap L\left(V_{2}\right) \neq \emptyset$.

Fig. 2. A. The graph $G\left(\mathcal{T}, \pi_{\top}\right)$ of the position $\pi_{\top}=\left(r_{1}, r_{2}, r_{3}\right)$ for the collection of trees of Figure 1. This graph is disconnected, the two connected components indicate the two successor positions $\pi_{1}=\left(p, r_{2}, w\right)$ and $\pi_{2}=(q, \perp, z)$ of $\pi_{\top}$. B. The graph $G\left(\mathcal{T}, \pi_{1}\right)$ is connected. Choosing a spanning tree (bold edges) of the graph and an arbitrary label shared by the two subtrees corresponding to the extremities of each edge of this tree identifies a conflict $C=\{a, b, c, d\}$.

Given a position $\pi$ in $\mathcal{T}$, we say that $\pi$ is compatible iff $\mathcal{T}(\pi)$ is compatible. Note that $\pi_{\perp}$ is compatible. Observe also that: $\pi$ is compatible iff $\pi \downarrow$ is compatible. Let us now consider a reduced position $\pi \neq \pi_{\perp}$. Then $|L(\pi)| \geq 2$. We have the following recursive characterization of compatibility for this case:

Lemma 3. Suppose that $|L(\pi)| \geq 2$. The following are equivalent:
$-\pi$ is compatible;

- there exists a partition $V_{1}, V_{2}$ of $V$ s.t. (i) $V_{1}, V_{2}$ are disconnected in $G(\mathcal{T}, \pi)$, (ii) $\operatorname{succ}_{V_{1}}(\pi)$, $\operatorname{succ}_{V_{2}}(\pi)$ are compatible.

Moreover, if the graph $G(\mathcal{T}, \pi)$ turns out to be connected, a spanning tree of this graph yields a small conflict between $\mathcal{T}$ :

Lemma 4. Suppose that $G(\mathcal{T}, \pi)$ is connected, and let $T=(V, F)$ be a spanning tree of $G(\mathcal{T}, \pi)$. For each edge $e=\{u, v\} \in F$, choose $l_{e} \in L(u) \cap L(v)$. Then $C=\left\{l_{e}: e \in F\right\}$ is a conflict between $\mathcal{T}$.

Lemmas 3 and 4 give rise to an algorithm for deciding the compatibility of a collection, and obtaining a conflict of small size in case of incompatibility:

Theorem 1. There is an algorithm which, in $O\left(k n^{2}\right)$ time, decides if $\mathcal{T}$ is compatible, or returns a conflict of size $\leq 2 k$.

Proof. We define a procedure IsCompatible( $\pi$ ) which takes as input a reduced position, decides if $\pi$ is compatible, or returns a conflict of size $\leq 2 k$ in case of incompatibility. The procedure is as follows: (i) answer ("yes") if $\pi=\pi_{\perp}$; (ii) if $\pi \neq \pi_{\perp}$, test whether $G(\mathcal{T}, \pi)$ is connected.

- If the graph is connected, then let $T=(V, F)$ be a spanning tree of $G(\mathcal{T}, \pi)$, choose $l_{e} \in L(u) \cap L(v)$ for each edge $e=\{u, v\} \in F$, construct $C=\left\{l_{e}: e \in F\right\}$, and return ("no", C).
- If the graph is not connected, then let $V_{1}, V_{2}$ be a partition of $V$ in two disconnected sets, and construct the positions $\pi_{1}, \pi_{2}$ where $\pi_{i}=\operatorname{succ}_{V_{i}}(\pi)$. Call IsCompatible $\left(\pi_{1}\right)$, let $R_{1}$ be its result; if $R_{1}=(" y e s ")$ then call $\operatorname{IsCompatible}\left(\pi_{2}\right)$ and return its result $R_{2}$, else return $R_{1}$.

To decide if $\mathcal{T}$ is compatible, we simply call IsCompatible $\left(\pi_{\top} \downarrow\right)$.
We now justify the correctness and the running time of the algorithm. The correctness of the procedure IsCompatible follows from lemmas 3 and 4 . For the running time, we rely on the fact that using appropriate data structures, we can ensure that a call to IsCompatible takes $O(k n)$ time (see Appendix for details). By lemmas 1 and 2, the total number of calls to IsCompatible is $O(n)$, therefore the total running time of the algorithm is $O\left(k n^{2}\right)$.

The algorithm of Theorem 1 yields a simple FPT algorithm for P-Smast using the bounded search tree technique:

Theorem 2. The P-Smast problem can be solved in $O\left((2 k)^{p} \times k n^{2}\right)$ time.

### 3.2 Solving Smast in $O\left((8 n)^{k}\right)$ time

In this section, we describe an algorithm which solves Smast in $O\left((8 n)^{k}\right)$ time. The algorithm uses dynamic programming, and is somewhat similar in spirit to the algorithm described in [8] for solving Mast on two trees.

We first give an alternative definition of the $\bowtie$ relation in terms of partial embeddings. Let $T, T^{\prime}$ be two trees, say that a partial embedding of $T$ into $T^{\prime}$ is a function $\phi: N(T) \rightarrow$ $N\left(T^{\prime}\right) \cup\{\perp\}$ such that:

- for any $x$ leaf of $T$, we have $\phi(x)=\perp$ if $x \notin L\left(T^{\prime}\right)$, or $\phi(x)=x$ otherwise,
- for any $x$ internal node of $T$ with children $u_{1}, \ldots, u_{p}$, let $V=\left\{j: \phi\left(u_{j}\right) \neq \perp\right\}$, then (i) either $V=\emptyset$, and $\phi(x)=\perp$, (ii) either $V=\{i\}$ and $\phi(x)=\phi\left(u_{i}\right)$, (ii) or $|V| \geq 2$ and $\phi(x)>_{T} \phi\left(u_{i}\right)$ for each $i \in V$, and the nodes $\left\{\operatorname{child}_{T}\left(\phi\left(u_{i}\right), \phi(x)\right): i \in V\right\}$ are pairwise distinct.

Then: $T \bowtie T^{\prime}$ iff there exists a partial embedding of $T$ into $T^{\prime}$ (or equivalently, a partial embedding of $T^{\prime}$ into $T$ ).

Given a collection $\mathcal{T}$, the algorithm computes values $\# S M A S T(\pi)$ for each position $\pi$. Let $S M A S T(\pi)$ denote the set of trees $T$ s.t. (i) $T$ is an agreement supertree for $\mathcal{T}$, (ii) for each $i$, the partial embedding $\phi_{i}: T \rightarrow T_{i}$ is such that $\phi_{i}(r(T)) \leq_{T_{i}} \pi[i]$. We denote by $\# S M A S T(\pi)$ the size of a largest tree of $S M A S T(\pi)$.

We now define two values $\# S M A S T_{1}(\pi)$ and $\# S M A S T_{2}(\pi)$, from which $\# S M A S T(\pi)$ is computed. We first define $\# S M A S T_{1}(\pi)$. Say that a position $\pi^{\prime}$ is a successor of $\pi$
iff there exists $i \in[k]$ s.t. $\pi^{\prime}[i]$ is a child of $\pi[i]$ and $\pi^{\prime}[j]=\pi[j]$ for each $j \neq i$. Let $S(\pi)$ denote the set of successors of $\pi$. Then:

$$
\begin{equation*}
\# S M A S T_{1}(\pi)=\max _{\pi^{\prime} \in S(\pi)} \# S M A S T\left(\pi^{\prime}\right) \tag{1}
\end{equation*}
$$

We now define \#SMAST $T_{2}(\pi)$. Say that a pair of positions $\left(\pi_{1}, \pi_{2}\right)$ is a decomposition of $\pi$ iff (i) $\pi_{1} \neq \pi, \pi_{2} \neq \pi$, (ii) for each $i \in[k]$, the following holds:

- either $\pi[i]=\perp$, in which case $\pi_{1}[i]=\pi_{2}[i]=\perp$;
- either $\pi[i]$ is a leaf $x$, in which case we have $\left\{\pi_{1}[i], \pi_{2}[i]\right\}=\{\perp, x\}$;
- either $\pi[i]$ is an internal node $u$ with two children $v, v^{\prime}$, in which case we have either $\left\{\pi_{1}[i], \pi_{2}[i]\right\}=\{\perp, x\}$ or $\left\{\pi_{1}[i], \pi_{2}[i]\right\}=\left\{v, v^{\prime}\right\}$.
Let $D(\pi)$ denote the set of decompositions of $\pi$. Then:

$$
\begin{equation*}
\# S M A S T_{2}(\pi)=\max _{\left(\pi_{1}, \pi_{2}\right) \in D(\pi)}\left(\# \operatorname{SMAST}\left(\pi_{1}\right)+\# \operatorname{SMAST}\left(\pi_{2}\right)\right) \tag{2}
\end{equation*}
$$

We define the relation $\leq_{\mathcal{T}}$ on $\Pi(\mathcal{T})$ by: $\pi \leq_{\mathcal{T}} \pi^{\prime}$ iff for each $i \in[k], \pi[i] \leq_{T_{i}} \pi^{\prime}[i]$. We observe that:

Lemma 5. (i) If $\pi^{\prime} \in S(\pi)$, then $\pi^{\prime}<_{\mathcal{T}} \pi$, (ii) if $\left(\pi_{1}, \pi_{2}\right) \in D(\pi)$ then $\pi_{i}<_{\mathcal{T}} \pi$ for $i \in\{1,2\}$.

Lemma 6. If $\pi^{\prime} \leq_{\mathcal{T}} \pi$, then $\operatorname{SMAST}\left(\pi^{\prime}\right) \subseteq \operatorname{SMAST}(\pi)$.
We now give a recurrence relation for computing $\# \operatorname{SMAST}(\pi)$. Say that a position $\pi$ is terminal if for each $i \in[k], \pi[i]$ is a leaf or $\perp$.

We first consider terminal positions. Given $x \in L(\mathcal{T})$, let $\operatorname{Ind}(x)=\{i \in[k]: x \in$ $\left.L\left(T_{i}\right)\right\}$. Given a terminal position $\pi$, and given $x \in L(\pi)$, define $\operatorname{Ind}(x, \pi)=\{i \in[k]$ : $\pi[i]=x\}$; observe that $\operatorname{Ind}(x, \pi) \subseteq \operatorname{Ind}(x)$. Say that an element $x \in L(\pi)$ is nice iff $\operatorname{Ind}(x, \pi)=\operatorname{Ind}(x)$, and let Nice $(\pi)$ denote the set of nice elements of $L(\pi)$. Then:

Lemma 7. Suppose that $\pi$ is terminal. Then: $\# \operatorname{SMAST}(\pi)=|\operatorname{Nice}(\pi)|$.
Lemma 8. Suppose that $\pi$ is not terminal. Then:
$\# S M A S T(\pi)=\max \left(\# \operatorname{SMAST}_{1}(\pi), \# \operatorname{SMAST}_{2}(\pi)\right)$.
Proof. We first prove that $\# S M A S T_{1}(\pi) \leq \# \operatorname{SMAST}(\pi)$. Let $S \in \operatorname{SMAST}\left(\pi^{\prime}\right)$ for some $\pi^{\prime} \in S(\pi)$, s.t. $|S|$ is maximal. Since $\pi^{\prime}<_{\mathcal{T}} \pi$ by Lemma 5 , we have $S \in \operatorname{SMAST}(\pi)$ by Lemma 6 , and the result follows.

We now prove that $\# \operatorname{SMAST}_{2}(\pi) \leq \# \operatorname{SMAST}(\pi)$. Let $\left(\pi_{1}, \pi_{2}\right) \in D(\pi)$, and let $S_{1}, S_{2}$ s.t. $S_{j} \in \operatorname{SMAST}\left(\pi_{i}\right),\left|S_{j}\right|$ maximal. If one of the $S_{j}$ 's is empty, say $S_{1}$, then $\# \operatorname{SMAST}\left(\pi_{1}\right)=0$, and we obtain $\# \operatorname{SMAST}_{2}(\pi)=\left|S_{2}\right|=\# \operatorname{SMAST}\left(\pi_{2}\right) \leq \# \operatorname{SMAST}(\pi)$
by lemmas 5 and 6 . Suppose now that $S_{1}, S_{2}$ are not empty. For $j \in\{1,2\}$, since $S_{j} \in$ $S M A S T\left(\pi_{j}\right)$, there exists partial embeddings $\phi_{j, i}: S_{j} \rightarrow T_{i}$ s.t. $\phi_{j, i}\left(r\left(S_{i}\right)\right) \leq_{T_{i}} \pi_{j}[i]$ for each $i \in[k]$. Let $S=\left(S_{1}, S_{2}\right)$, we claim that $S \in S M A S T(\pi)$. Indeed, define $\phi_{i}: S \rightarrow T_{i}$ as follows. Set $\phi_{i}(x)=\phi_{j, i}(x)$ if $x$ is a node of $S_{j}$, and $\phi_{i}(x)=\operatorname{lca}_{T_{i}}\left(\phi_{1, i}\left(r\left(S_{1}\right)\right), \phi_{2, i}\left(r\left(S_{2}\right)\right)\right.$ if $x$ is the root of $S$. It is clear that: (i) $L\left(S_{1}\right) \cap L\left(S_{2}\right)=\emptyset$, hence $S$ is well-defined, (ii) $\phi_{i}$ is a partial embedding of $S$ into $T_{i}$, (iii) $\phi_{i}(r(S)) \leq_{T_{i}} \pi[i]$ (proof in Appendix). We conclude that $\# S M A S T_{2}(\pi)=\left|S_{1}\right|+\left|S_{2}\right|=|S| \leq \# S M A S T(\pi)$.

Finally, we show that $\# S M A S T(\pi) \leq \max \left(\# S M A S T_{1}(\pi), \# S M A S T_{2}(\pi)\right)$. Let $S \in$ $S M A S T(\pi)$ s.t. $|S|$ is maximal. Then there exists partial embeddings $\phi_{i}: S \rightarrow T_{i}$ s.t. $\phi_{i}(r(S)) \leq_{T_{i}} \pi[i]$ for each $i \in[k]$. Let $u_{i}=\phi_{i}(r(S))$ for each $i$. We consider two cases.

First case: there exists $i \in[k]$ s.t. $u_{i}<_{T_{i}} \pi[i]$. This case holds in particular if $|S| \leq$ 1. Define $\pi^{\prime}$ from $\pi$ by setting the $i$ th component to child $T_{i}\left(u_{i}, \pi[i]\right)$, then $\pi^{\prime} \in S(\pi)$. We verify that $S \in S M A S T\left(\pi^{\prime}\right)$ : indeed, $\phi_{i}$ is a partial embedding of $S$ into $T_{i}$ s.t. $\phi_{i}(r(S)) \leq_{T_{j}} \pi^{\prime}[j]$ for each $j$. We conclude that $|S|=\# S M A S T(\pi) \leq \# S M A S T\left(\pi^{\prime}\right) \leq$ $\# S M A S T_{1}(\pi)$.

Second case: $u_{i}=\pi[i]$ for each $i \in[k]$. In this case, we have $|S| \geq 2$, hence $S=$ $\left(S_{1}, S_{2}\right)$. Let $u$ be the root of $S$, let $v_{i}$ be the root of $S_{i}$ in $S$, then $\pi=\left(\phi_{1}(u), \ldots, \phi_{k}(u)\right)$. For $j \in\{1,2\}$, define $\pi_{j}$ as follows: given $i \in[k]$, (i) if $\phi_{i}\left(v_{j}\right)=\phi_{i}(u)$, set $\pi_{j}[i]=\phi_{i}(u)$, (ii) if $\phi_{i}\left(v_{j}\right)=\perp$, set $\pi_{j}[i]=\perp$, (iii) if $\phi_{i}\left(v_{j}\right)<T_{i} \phi_{i}(u)$, set $\pi_{j}[i]=\operatorname{child}_{T_{i}}\left(\phi_{i}\left(v_{j}\right), \phi_{i}(u)\right)$. It is clear that $\left(\pi_{1}, \pi_{2}\right) \in D(\pi)$ (proof in Appendix). We now show that $S_{j} \in S M A S T\left(\pi_{j}\right)$ : indeed, $\phi_{i}$ is a partial embedding of $S_{j}$ into $T_{i}$, and by definition of $\pi_{j}$ we have $\phi_{i}\left(r\left(S_{j}\right)\right) \leq_{T_{i}}$ $\pi_{j}[i]$ for each $i \in[k]$. We conclude that $|S|=\# S M A S T(\pi)=\left|S_{1}\right|+\left|S_{2}\right| \leq \# S M A S T\left(\pi_{1}\right)+$ $\# S M A S T\left(\pi_{2}\right) \leq \# S M A S T_{2}(\pi)$.

Lemmas 7 and 8 yield an algorithm for computing $\# S M A S T(\mathcal{T})$ :
Theorem 3. \#SMAST $(\mathcal{T})$ can be computed in $O\left((8 n)^{k}\right)$ time.
Proof. Using dynamic programming, the algorithm computes the values \#SMAST( $\pi$ ) for each position $\pi$, using the recurrence relations stated in lemmas 7 and 8 . The correctness of the algorithm follows from the lemmas, and the termination of the algorithm is ensured by Lemma 5 and the fact that $<_{\mathcal{T}}$ is an order relation on $\Pi(\mathcal{T})$.

We now consider the space and time requirements for the algorithm. First observe that the number of positions $\pi$ in $\mathcal{T}$ is $\leq(2 n)^{k}$ : indeed, a component $\pi[i]$ has $\leq 2 n$ possible values (one of the $\leq 2 n-1$ nodes of $T_{i}$, or the value $\perp$ ). It follows that the space complexity is $O\left((2 n)^{k}\right)$. We claim that the time complexity is $O\left((8 n)^{k}\right)$. Indeed, consider the time required to compute $\# S M A S T(\pi)$, assuming that the values $\# S M A S T\left(\pi^{\prime}\right)$ for $\pi^{\prime}<_{\mathcal{T}} \pi$ are available. Testing if $\pi$ is terminal requires $O(k)$ time. If $\pi$ is terminal, computing $|\operatorname{Nice}(\pi)|$ takes $O(k)$ time. If $\pi$ is nonterminal, then we need to compute $\# S M A S T_{1}(\pi)$ and $\# S M A S T_{2}(\pi)$, which respectively require $O(k)$ and $O\left(4^{k}\right)$ time. Thus, $\# S M A S T(\pi)$ is computed in $O\left(4^{k}\right)$ time, hence the total running time of the algorithm is $O\left((8 n)^{k}\right)$.

### 3.3 Hardness results

The parameterized complexity of the Smast problem on binary trees is considered w.r.t. the following parameters: $k$ denotes the number of input trees, $l$ denotes an upper bound on the maximum size of the input trees, $p$ (resp. $q$ ) denotes an upper (resp. lower) bound on the number of labels to remove (resp. conserve) in order to obtain compatibility of the collection. Our complexity results for several combinations of the parameters are summarized in Theorem 4:

Theorem 4. We have the following hardness results for Smast:

| Parameters | Complexity of SmAST |
| :--- | :--- |
| $q$ | $\mathrm{~W}[1]$-complete (even for $l=3)$ |
| $q, k$ | $\mathrm{~W}[1]$-complete (even for $l=3)$ |
| $p$ | $\mathrm{~W}[2]$-hard (even for $l=3)$ |
| $k, p$ | FPT by a $O\left((2 k)^{p} \times k n^{2}\right)$ time algorithm |
| $k$ | XNL-hard, solvable in $O\left((8 n)^{k}\right)$ time |

## 4 Solving Smast on complete collection of triples

A rooted triple (or triple for short) is a binary tree $T$ s.t. $|L(T)|=3$. A collection of triples is a collection $\mathcal{R}=\left\{t_{1}, \ldots, t_{k}\right\}$ where each $t_{i}$ is a triple. $\mathcal{R}$ is complete iff each set of three labels in $L(\mathcal{R})$ is present in at least one $t_{i}$. To a binary tree $T$, we associate a complete collection of triples $r t(T)$ formed by the triples $t_{i} \leq T$. For a complete collection $\mathcal{R}$, we say that $\mathcal{R}$ is treelike iff there exists a tree $T$ s.t. $\mathcal{R}=r t(T)$; then we say that $\mathcal{R}$ displays $T$.

Let P-Smast-CR denote the restriction of P-Smast to complete collections of triples. We can show that non-treelike collections have conflicts of size $\leq 4$, a result similar to that known on quartets [11]. This allows to solve P-SmAST-CR in $O\left(n^{4}+3.12^{p}\right)$ time by reduction to 4 -Hitting SEt [12]. and also in $O\left(4^{p} n^{4}\right)$ time by bounded search (see, e.g. [13]). In the following, we describe a faster algorithm with $O\left(4^{p} n^{3}\right)$ running time. We first present an algorithm to decide treelikeness in linear $O\left(n^{3}\right)$ time (Proposition 1 and Theorem 5).

Proposition 1. There is an algorithm Insert-Label-Or-Find-Conflict $(\mathcal{R}, X, x, T)$ which takes a complete collection of triples $\mathcal{R}$, a set $X \subseteq L(\mathcal{R})$, an element $x \in L(\mathcal{R}) \backslash X$ and a tree $T$ s.t. $\mathcal{R} \mid X$ displays $T$, and in $O\left(n^{2}\right)$ time decides if $\mathcal{R}^{\prime}=\mathcal{R} \mid(X \cup\{x\})$ is treelike. Additionally, the algorithm returns the tree $T^{\prime}$ displayed by $\mathcal{R}^{\prime}$ in case of positive answer, or returns a conflict $C$ between $\mathcal{R}^{\prime}$ with $|C| \leq 4$ in case of negative answer.

Proof. In a first step, the algorithm checks whether $\mathcal{R}$ contains two different triples on the same set of three labels $x, \ell, \ell^{\prime}$. In such a case, they form a conflict of size 3 which is
then returned by the algorithm. Suppose now that no such conflict is found. Let $u$ be an internal node of $T$, and let $v, v^{\prime}$ be the two children of $u$. An $u$-fork is a pair $\left\{l, l^{\prime}\right\}$ where $l \in L(v), l^{\prime} \in L\left(v^{\prime}\right)$. Each $u$-fork $\left\{l, l^{\prime}\right\}$ will propose a status $s_{l, l^{\prime}}$ for the positioning of $x$ w.r.t. $u$ in $T$, where $s_{l, l^{\prime}}$ is computed from $\mathcal{R}$ as follows: $s_{l, l^{\prime}}=L$ if $l x \mid l^{\prime} \in \mathcal{R}, s_{l, l^{\prime}}=R$ if $l^{\prime} x \mid l \in \mathcal{R}, s_{l, l^{\prime}}=U$ if $l l^{\prime} \mid x \in \mathcal{R}(L, R, U$ respectively stand for left, right and up).

The second step of the algorithm consists in successively considering each internal node $u$. For a given node $u$, it checks that the different $u$-forks propose the same status. This verification is performed as follows: (i) for each $u$-fork $\left\{l, l^{\prime}\right\}$, determine the status $s_{l, l^{\prime}}$; (ii) if there exists $l, l_{1}^{\prime}, l_{2}^{\prime}$ s.t. $s_{l, l_{1}^{\prime}} \neq s_{l, l_{2}^{\prime}}$, then $C=\left\{x, l, l_{1}^{\prime}, l_{2}^{\prime}\right\}$ is a conflict; (iii) if there exists $l_{1}, l_{2}, l^{\prime}$ s.t. $s_{l_{1}, l^{\prime}} \neq s_{l_{2}, l^{\prime}}$, then $C=\left\{x, l_{1}, l_{2}, l^{\prime}\right\}$ is a conflict; (iv) else, all values $s_{l, l^{\prime}}$ are identical, let $s_{u}$ denote this value.

In a third step, the algorithm checks that the different statuses are compatible. They are compatible iff for each edge $u, v$ of $T$ with $u$ above $v$, we have: (i) if $v$ is the left child of $u$, then $s_{u}=R \Rightarrow s_{v}=U$, (ii) if $v$ is the right child of $u$, then $s_{u}=L \Rightarrow s_{v}=U$, (iii) if $v$ is a child of $u$, then $s_{u}=U \Rightarrow s_{v}=U$. If one pair of nodes $u, v$ does not meet the above requirements, then by considering $\left\{l, l^{\prime}\right\} v$-fork and $\left\{l, l^{\prime \prime}\right\} u$-fork, we obtain a conflict $C=\left\{x, l, l^{\prime}, l^{\prime \prime}\right\}$. Otherwise, consider the sets of nodes $u$ s.t. $s_{u} \neq U$, they form a (possibly empty) path in $T$ starting at the root and ending at a node $v$. Then $\mathcal{R} \mid(X \cup\{x\})$ is treelike, and displays the tree obtained from $T$ by inserting $x$ above $v$, which is returned by the algorithm.

We now justify the running time of the algorithm. The first step trivially takes $O\left(n^{2}\right)$ time. Consider the second step. Given a node $u$, let $F_{u}$ be the set of $u$-forks, then an internal node $u$ is processed in time $O\left(\left|F_{u}\right|\right)$. Therefore, the time required by the second step is $\sum_{u} O\left(\left|F_{u}\right|\right)=O\left(n^{2}\right)$. Now consider the third step. The algorithm checks that for each edge $u, v$ of $T$, Conditions (i)-(ii)-(iii) hold: for a given edge, checking the conditions or finding a conflict is done in constant time, hence the time required by this step is $O(n)$. It follows that the total time required by the algorithm is $O\left(n^{2}\right)$.

Theorem 5. There is an algorithm Find-Tree-Or-Conflict( $\mathcal{R}$ ) which takes a complete collection of triples $\mathcal{R}$, and in $O\left(n^{3}\right)$ time decides if $\mathcal{R}$ is treelike, returns a tree $T$ displayed by $\mathcal{R}$ in case of positive answer, or a conflict $C$ between $\mathcal{R}$ with $|C| \leq 4$ in case of negative answer.

Proof. We use the procedure Insert-Label-Or-Find-Conflict to decide treelikeness as follows. We iteratively insert each label, starting from an empty tree, until: (i) either every label has been inserted, in which case the collection is treelike and the displayed tree is returned, (ii) or a conflict is found and returned.

Using bounded search, we obtain:
Theorem 6. The P-Smast-CR problem can be solved in $O\left(4^{p} n^{3}\right)$ time.

## 5 Appendix

We give below proofs for some results stated in the paper. Proofs for other results can be found in [14]. We first establish a preliminary lemma.

Lemma 9. Suppose that $\mathcal{T}=\left\{T_{1}, \ldots, T_{k}\right\}$ is compatible. Then:

1. for each $L \subseteq L(\mathcal{T}), \mathcal{T} \mid L$ is compatible.
2. for each position $\pi$ in $\mathcal{T}, \mathcal{T}(\pi)$ is compatible.

Proof. Let $S$ be a total agreement supertree for $\mathcal{T}$.
To prove Point 1 , consider $L \subseteq L(\mathcal{T})$. Then for each $i \in[k]$ we have $T_{i} \leq S \Rightarrow T_{i} \mid L \leq$ $S \mid L$. Hence $S \mid L$ is a total agreement supertree for $\mathcal{T} \mid L$.

To prove Point 2, consider a position $\pi$ in $\mathcal{T}$. Remark that $\mathcal{T} \mid L(\pi)$ is compatible by Point 1 . Let $S$ be a total agreement supertree for $\mathcal{T} \mid L(\pi)$, we claim that $S$ is a total agreement supertree for $\mathcal{T}(\pi)$. Indeed, we have $L(S)=L(\pi)=L(\mathcal{T}(\pi))$, and given $i \in[k]$ we have $T_{i}\left(u_{i}\right) \leq T_{i} \mid L(\pi) \leq S$.

Proof of Lemma $3(\Rightarrow)$. Suppose that $\pi$ is compatible. Let $S$ be a total agreement supertree for $\mathcal{T}(\pi)$. Since $\mid L(\pi)) \mid \geq 2$, we have $S=\left(S_{1}, S_{2}\right)$. Since $S$ is a total agreement supertree for $\mathcal{T}(\pi)$, we have $T_{i}(\pi[i]) \leq S$ for each $i \in[k]$. Define a partition $V_{1}, V_{2}$ of $V$ as follows. Let $u_{i}=\pi[i]$, and suppose that $u_{i}$ is an internal node of $T_{i}$, with children $v_{i}, v_{i}^{\prime}$. Then $T_{i}\left(u_{i}\right)=\left(T_{i}\left(v_{i}\right), T_{i}\left(v_{i}^{\prime}\right)\right)$. Together with $T_{i}\left(u_{i}\right) \leq S$, this yields $T_{i}\left(v_{i}\right) \leq S_{1}$ or $T_{i}\left(v_{i}\right) \leq S_{2}$ : add $v_{i}$ to $V_{1}$ in the first case, to $V_{2}$ in the second case. Proceed similarly for $v_{i}^{\prime}$.

We first prove Point (i). To see that $V_{1}, V_{2}$ are disconnected in $G(\mathcal{T}, \pi)$, observe that $L\left(V_{1}\right) \subseteq L\left(S_{1}\right)$ and $L\left(V_{2}\right) \subseteq L\left(S_{2}\right)$. Indeed, if $x \in V_{j}$ with $x \in\left\{v_{i}, v_{i}^{\prime}\right\}$ then $T_{i}(x) \leq S_{j}$, hence $L(x) \subseteq L\left(S_{j}\right)$. It follows that $V_{1}, V_{2}$ are disconnected by Lemma 2 . We now prove Point (ii). Let $\pi_{j}=\operatorname{succ}_{V_{j}}(\pi)$, then $\pi_{j}$ is a position in $\mathcal{T}(\pi)$, and since $\mathcal{T}(\pi)$ is compatible by assumption, it follows that $\pi_{j}$ is compatible by Point 2 of Lemma 9 .
$(\Leftarrow)$. Suppose that there exists a partition $V_{1}, V_{2}$ of $V$ satisfying Points (i), (ii). Let $\pi_{j}=\operatorname{Succ}_{V_{j}}(\pi)$. Since $\operatorname{succ}_{V_{j}}(\pi)$ is compatible, it follows that $\pi_{j}$ is compatible. Hence, there exists a total agreement supertree $S_{j}$ for $\mathcal{T}\left(\pi_{j}\right)$, which thus satisfies: $T_{i}\left(\pi_{j}[i]\right) \leq$ $S_{j}$ for each $i$. By Lemma 1, we then have $L\left(S_{j}\right)=L\left(\pi_{j}\right) \subseteq L\left(V_{j}\right)$. Since $V_{1}, V_{2}$ are disconnected in $G(\mathcal{T}, \pi)$, it follows that $L\left(V_{1}\right) \cap L\left(V_{2}\right)=\emptyset$ by Lemma 2. Therefore we have $L\left(S_{1}\right) \cap L\left(S_{2}\right)=\emptyset$, and we can define the tree $S=\left(S_{1}, S_{2}\right)$. We show that $S$ is a total agreement supertree for $\mathcal{T}(\pi)$ : to this end, we need to show that $T_{i}(\pi[i]) \leq S$ for each $i \in[k]$.

Fix such an $i$, let $u_{i}=\pi[i]$. If $u_{i}=\perp$, then the relation holds obviously. Suppose now that $u_{i}$ is an internal node of $T_{i}$, and let $v_{i}, v_{i}^{\prime}$ be its two children. We consider three cases. If $v_{i}, v_{i}^{\prime} \in V_{1}$ : then $\pi_{1}[i]=u_{i}$, therefore we have $T_{i}\left(u_{i}\right) \leq S_{1}$, and we conclude that $T_{i}\left(u_{i}\right) \leq S$. If $v_{i}, v_{i}^{\prime} \in V_{2}$ : then $\pi_{2}[i]=u_{i}$, therefore we have $T_{i}\left(u_{i}\right) \leq S_{2}$, and we conclude that $T_{i}\left(u_{i}\right) \leq S$. If $v_{i} \in V_{1}, v_{i}^{\prime} \in V_{2}$ : then $\pi_{1}[i]=v_{i}$, which implies that $T_{i}\left(v_{i}\right) \leq S_{1}$, and $\pi_{2}[i]=v_{i}^{\prime}$, which implies that $T_{i}\left(v_{i}^{\prime}\right) \leq S_{2}$. It is easy to see that $T_{i}\left(v_{i}\right) \leq S_{1}$ and $T_{i}\left(v_{i}^{\prime}\right) \leq S_{2}$ imply that $T_{i}\left(u_{i}\right)=\left(T_{i}\left(v_{i}\right), T_{i}\left(v_{i}^{\prime}\right)\right) \leq\left(S_{1}, S_{2}\right)=S$.

Proof of Lemma 4: We show that $\mathcal{T}^{\prime}=\mathcal{T} \mid C$ is incompatible. For each $i \in I(\pi)$, let $u_{i}=$ $\pi[i]$, and let $v_{i}, v_{i}^{\prime}$ be its two children in $T_{i}$. By definition of $C$, the sets $L\left(v_{i}\right) \cap C, L\left(v_{i}^{\prime}\right) \cap C$ are not empty, hence to the nodes $v_{i}, v_{i}^{\prime}, u_{i}$ there corresponds nodes $\tilde{v}_{i}, \tilde{v}_{i}^{\prime}, \tilde{u}_{i}$ in $T_{i} \mid C$. Define the position $\pi^{\prime}$ by setting $\pi^{\prime}[i]=\perp$ if $i \notin I(\pi), \pi^{\prime}[i]=\tilde{u}_{i}$ if $i \in I(\pi)$. Consider the graph $G\left(\mathcal{T}^{\prime}, \pi^{\prime}\right)$, then by definition of $C$ for each edge $\{x, y\}$ of $T$, the edge $\{\tilde{x}, \tilde{y}\}$ is present in $G\left(\mathcal{T}^{\prime}, \pi^{\prime}\right)$, therefore the tree $T^{\prime}$ formed of these edges is a spanning tree of $G\left(\mathcal{T}^{\prime}, \pi^{\prime}\right)$, hence the graph is connected. By Lemma 3, we conclude that $\pi^{\prime}$ is an incompatible position of $\mathcal{T}^{\prime}$, therefore $\mathcal{T}^{\prime}$ is incompatible (by Point 2 of Lemma 9).

End of the proof of Theorem 1. We show that the procedure IsCompatible can be implemented as a $O(k n)$ time algorithm. Obviously, (i) testing if $\pi=\pi_{\perp}$ is done in $O(k)$ time, (ii) given $T$ spanning tree of $G(\mathcal{T}, \pi)$, constructing $C$ is done in $|T|=O(k)$ time, provided we have stored a label $l_{e}$ for each edge of $T$, (iii) given $V_{1}, V_{2}$ partition of $V$, constructing the positions $\pi_{1}, \pi_{2}$ is done in $O(k)$ time. We now justify that in $O(k n)$ time we can perform a connexity test on $G(\mathcal{T}, \pi)$.

The crucial point is that the algorithm tests the connexity of the graph, by working on the intersection model of $G:=G(\mathcal{T}, \pi)$ provided by the sets $\{L(x): x \in V\}$. In this way, we avoid constructing the adjacency matrix of $G$, which would require $O\left(k^{2} n\right)$ time. We thus need to describe a connexity test for a graph $G=(V, E)$ given by an intersection model $\left\{S_{v}: v \in V\right\}$, where the $S_{v}$ are subsets of a base set $S$. We will justify that the algorithm has running time $O(k n)$, where $k=|V|$ and $n=|S|$.

The algorithm proceeds as follows. It performs a traversal of the graph, by starting at an arbitrary vertex $u \in V$, and maintains the following information during the traversal: (i) the set $U$ of nodes already visited, (ii) a set $F$ of edges forming a spanning tree of $G[U]$. At each step, the algorithm seeks a transverse edge, which is an edge $e=\{u, v\} \in E$ with $u \in U, v \in \bar{U}$. If such an edge is found, then $y$ is added to $U$, and $e$ is added to $F$. If no such edge exists, the algorithm stops, and the graph is connected iff $U=V$.

We show that using appropriate data structures, a step of the algorithm can be done in $O(n)$ time. For each $x \in S$, let $V_{x}=\left\{v \in V: x \in S_{v}\right\}$. We maintain for each $x \in S$, two lists representing the sets $U_{x}=V_{x} \cap U$ and $\bar{U}_{x}=V_{x} \cap \bar{U}$. Initializing these lists at the beginning of the algorithm is done in $O(k n)$ time. Moreover, at a given step of the algorithm: (i) we can find a tranversal edge in $O(n)$ time, (ii) we can update the structures in $O(n)$ time. To justify Point (i), observe that finding a transversal edge amounts to find an element $x \in S$ s.t. $U_{x}, \bar{U}_{x}$ are non empty; if such an $x$ is found then by choosing $u \in U_{x}, v \in \bar{U}_{x}$ we obtain a transverse edge $\{u, v\}$; clearly, these operations can be performed in $O(n)$ time. To justify Point (ii), observe that when visiting a new vertex $v$, we need, for each $x \in S_{v}$, to add $v$ to $U_{x}$ and to remove $v$ from $\bar{U}_{x}$, which can be performed in $O(n)$ time by using appropriate linkage.

End of the proof of Lemma 8.
(i) $L\left(S_{1}\right) \cap L\left(S_{2}\right)=\emptyset$ : indeed, if there was $x \in L\left(S_{1}\right) \cap L\left(S_{2}\right)$ then we would have $x \in L\left(T_{i}\right)$ for some $i \in[k]$; then $x=\phi_{j, i}(x) \leq_{T_{i}} \pi_{j}[i]$. Since $x \in L\left(T_{i}\right)$, we must have $\pi_{1}[i], \pi_{2}[i] \neq \perp$; then they are equal to distinct children of $\pi[i]$, impossible.
(ii) $\phi_{i}$ is a partial embedding of $S$ into $T_{i}$ :

- if $x \in L(S)$, then $x \in L\left(S_{j}\right)$. We conclude using the fact that $\phi_{j, i}$ is a partial embedding and that $\phi_{i}(x)=\phi_{j, i}(x)$.
- if $x$ is an internal node of $S$ with children $x^{\prime}, x^{\prime \prime}$, then:
- if $x \in N\left(S_{j}\right)$, we conclude using the fact that $\phi_{j, i}$ is a partial embedding and that $\phi_{i}(x)=\phi_{j, i}(x)$.
- if $x=r(S)$, with children $x^{\prime}=r\left(S_{1}\right), x^{\prime \prime}=r\left(S_{2}\right)$ : then
* either $\phi_{1, i}\left(x^{\prime}\right)=\phi_{2, i}\left(x^{\prime \prime}\right)=\perp$, in which case $\phi_{i}(x)=\perp$;
* either $\phi_{1, i}\left(x^{\prime}\right) \neq \perp, \phi_{2, i}\left(x^{\prime \prime}\right)=\perp$, in which case $\phi_{i}(x)=\phi_{1, i}\left(x^{\prime}\right)$;
* either $\phi_{1, i}\left(x^{\prime}\right)=\perp, \phi_{2, i}\left(x^{\prime \prime}\right) \neq \perp$, in which case $\phi_{i}(x)=\phi_{2, i}\left(x^{\prime \prime}\right)$;
* either $\phi_{1, i}\left(x^{\prime}\right) \neq \perp, \phi_{2, i}\left(x^{\prime \prime}\right) \neq \perp$, in which case these are nodes $y^{\prime}, y^{\prime \prime}$ s.t. $y^{\prime} \leq_{T_{i}}$ $\pi_{1}[i], y^{\prime \prime} \leq_{T_{i}} \pi_{2}[i]$. Since $\left(\pi_{1}, \pi_{2}\right) \in D(\pi)$, it follows that $\pi_{1}[i], \pi_{2}[i]$ are $\neq \perp$ and are distinct children of $\pi[i]$, hence $\phi_{i}(x)=\pi[i]$, which implies that $\phi_{1, i}\left(x^{\prime}\right)<T_{i}$ $\phi_{i}(x), \phi_{2, i}\left(x^{\prime \prime}\right)<_{T_{i}} \phi_{i}(x)$.
(iii) $\phi_{i}(r(S)) \leq T_{i} \pi[i]$ : follows from the definition of $\phi_{i}(r(S))$ and from the fact that $\phi_{i}\left(r\left(S_{j}\right)\right) \leq_{T_{i}} \pi_{j}[i]$.

We show that $\left(\pi_{1}, \pi_{2}\right) \in D(\pi)$. Indeed, (i) we have $\pi_{j} \neq \pi$ since if we had $\pi_{1}[i]=\pi[i]$ for each $i$, this would imply $\pi_{2}[i]=\perp$ for each $i$, but given $x \in L\left(S_{2}\right)$ there exists $i$ s.t. $x \in L\left(T_{i}\right)$, impossible; (ii) fix $i \in[k]$ :

- if $\pi[i]=\perp$, then $\phi_{i}(u)=\perp$, and we then have $\phi_{i}\left(v_{1}\right)=\phi_{i}\left(v_{2}\right)=\perp$ by definition of a partial embedding, hence $\pi_{1}[i]=\pi_{2}[i]=\perp$;
- if $\pi[i] \neq \perp$, then $\phi_{i}(u)$ is a node of $T_{i}$, and we have:
- either $\phi_{i}\left(v_{1}\right), \phi_{i}\left(v_{2}\right) \neq \perp$, in which case the nodes child $T_{i}\left(\phi_{i}\left(v_{1}\right), \phi_{i}(u)\right)$, $\operatorname{child}_{T_{i}}\left(\phi_{i}\left(v_{2}\right), \phi_{i}(u)\right)$ are distinct, which implies that $\pi_{1}[i], \pi_{2}[i]$ are distinct children of $\pi[i]$;
- or one of $\phi_{i}\left(v_{1}\right), \phi_{i}\left(v_{2}\right)$ is equal to $\perp$, in which case the other must be equal to $\phi_{i}(u)$, which implies that $\pi_{1}[i]=\pi[i], \pi_{2}[i]=\perp$ or the symmetric case.
