L'archive ouverte pluridisciplinaire **HAL**, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d'enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.

A discrete-time control strategy for dynamic walking of a planar under-actuated biped robot

Ahmed Chemori

Abstract—This paper deals with a discret-time control approach, proposed for the control of a five-link, four-actuator planar biped walker. The approach is based on the choice of a particular class of walk configurations that enables a full state controllability avoiding the need to use Poincaré-like argumentation in the proof of motion’s reproducibility (stability of limit cycles). Simulation results attest the efficiency of the proposed control approach.

I. INTRODUCTION

In last the decades, the robotics community has shown increasing interest in the area of legged walking robots [14], [1]. An excellent database of biped walking robots built all over the world can be found in [1]. One of the serious reasons for exploring the use of walking robots relies in the fact that they can co-exist and collaborate with their creators without any costly modification to the environment created for humans.

Currently, many research groups over the world are working on biped robots, either on optimization of leg and foot trajectory, stable walking control, or hardware design. The main thrust of current research on biped control includes many proposed control approaches, such as passivity based control [16], robust sliding mode control [3], impedance control [12], nonlinear predictive control [4], optimal control [8], Lyapunov based control [5] computed torque control [2], tracking control [15], intuitive control [13], intelligent learning control [11], and neural network control [10].

From a control point of view, the major interest of biped robots comes from the following difficulties that are inherent to control of such systems:

- 1) biped robots have generally high degrees of freedom mechanical structure, therefore many links and joints are to be coordinated to achieve walking gaits,
- 2) dynamics of biped robots includes high nonlinearities,
- 3) their hybrid nature resulting from impacts with the ground producing discontinuities (jumps) in the generalized velocities,
- 4) another interesting point is under-actuation. Biped walking robots may be under-actuated (case of our robot Rabbit) that is the number of actuators is fewer than the number of degrees of freedom (d.o.f),
- 5) the variable structure resulting from the switching between different walking phases.

In this paper a new control strategy is proposed to control a five-link, four-actuator biped walking robot. The directly

controlled d.o.f are the *absolute* angular positions of the lower-limbs of the robot $X_c = (\pi - q_{31}, \pi - q_{32}, q_{41}, q_{42})^T$, whereas the indirectly controlled d.o.f is the position of the torso defined by $X_{nc} = q_1$ (unactuated coordinate). The main idea consists in the choice of particular configurations, for which the dynamics of the system is linearized. Then a discret-time feedback is proposed to control the whole system to produce stable cyclic walking gaits.

This paper is organized as follows. The first section is this introduction. In section II, the biped robot prototype is described, and its dynamical model is discussed. Section III is devoted to the unactuated coordinate dynamics. The proposed control strategy is detailed in section IV. Numerical simulations are given in section V to illustrate the efficiency of the proposed control strategy. Finally, concluding remarks are drawn in section VI.

II. ROBOT DESCRIPTION AND DYNAMICS

Illustrated by the schematic view on figure 1, RABBIT has two legs and a torso. It has the original specificity enabling both walking and running gaits [6]. Thanks to a guidance device, the robot is laterally stabilized, then its motions can be considered in the sagittal plane.

The mechanical structure of the robot is illustrated on figure 2 showing its generalized coordinates and control inputs. The

Fig. 1. Schematic view of the biped RABBIT

Fig. 2. RABBIT’s mechanical structure

use of Lagrange formulation [17] enables the computation of the nonlinear dynamic model of the robot moving in the sagittal plane without contact with the ground:

$$M(q)\ddot{q} + N(q, \dot{q})\dot{q} + G(q) = Su \quad (1)$$

where $M(q) \in \mathbb{R}^{7 \times 7}$ is the inertia matrix, $N(q, \dot{q}) \in \mathbb{R}^{7 \times 7}$ is the matrix of the centrifugal and Coriolis forces, $G(q) \in \mathbb{R}^7$

A. Chemori is with LIRMM, Univ. Montpellier 2 - CNRS, 161 rue Ada, 34392 Montpellier, France chemori@lirmm.fr

is the vector of gravitational forces, $u \in \mathbb{R}^4$ is the vector of control inputs, $S \in \mathbb{R}^{7 \times 4}$ is a torque distribution matrix, $q = (q_{31} \ q_{41} \ q_{32} \ q_{42} \ q_1 \ x \ y)^T \in \mathbb{R}^7$ is the vector of generalized coordinates of the robot (cf. figure 2). The walking cycle of the biped can be decomposed into three walking phases, namely the *swing phase* (or single support phase), the *impact phase* and the *double support phase*. In the case of this study the double support phase is assumed to be instantaneous as in [7], [4] and others. The control of the biped robot on the whole walking cycle needs the computation of its dynamic model on the different walking phases. This is the subject of forthcoming sections.

A. The swing phase model

The dynamic model describing the biped robot in the swing phase is given by the following:

$$\begin{cases} M(q)\ddot{q} + N(q, \dot{q})\dot{q} + G(q) = Su + J_1^T(q)\lambda \\ J_1(q)\ddot{q} + \frac{\partial^2 \Phi_1}{\partial q^2} \dot{q}^2 = 0 \end{cases} \quad (2)$$

where λ is the Lagrange multipliers of the contact forces, $\Phi_1(q)$ is the function of the contact constraints, and $J_1(q)$ is their Jacobian matrix.

B. The impact phase model

Under the assumption that the swing foot and the ground are rigid bodies, the end of the swing phase is characterized by a collision between the swing foot and the ground [18]. The application of the non-regular mechanics laws enables us to deduce the dynamic model of the rigid impact that happens between the swing-leg foot and the ground [9]:

$$\begin{cases} \dot{q}^+ = \left[I - M^{-1} J_2^T (J_2 M^{-1} J_2^T)^{-1} J_2 \right] \dot{q}^- = D(q) \dot{q}^- \\ \lambda = - \left[(J_2 M^{-1} J_2^T)^{-1} J_2 \right] \dot{q}^- \end{cases} \quad (3)$$

It gives \dot{q}^+ and λ as functions of the pre-impact positions q^- and velocities \dot{q}^- . This dynamics may be expressed as:

$$\begin{pmatrix} q^+ \\ \dot{q}^+ \end{pmatrix} = \Delta(q) \begin{pmatrix} q^- \\ \dot{q}^- \end{pmatrix} \quad (4)$$

where the matrix $\Delta(q)$ includes also the relabeling of the legs (i.e the stance leg becomes a swing leg and vice versa).

III. DYNAMICS OF THE TORSO

Let us consider the dynamic model (1) of the robot. Extracted from it, the dynamics of the torso is given by:

$$\begin{aligned} \left(\frac{1}{4} m_1 l_1^2 + I_1 \right) \ddot{q}_1 &= \frac{1}{2} m_1 l_1 \cos(q_1) \ddot{x} + \\ &\frac{1}{2} m_1 l_1 \sin(q_1) (\ddot{y} + g) - u_1 - u_2 \end{aligned} \quad (5)$$

where u_1 and u_2 are the control inputs of articulations q_{31} and q_{32} respectively, whose dynamics is given by:

$$\begin{aligned} M_1(q) \begin{pmatrix} \ddot{q}_{31} \\ \ddot{q}_{32} \end{pmatrix} + M_2(q) \begin{pmatrix} \ddot{q}_{41} \\ \ddot{q}_{42} \end{pmatrix} + M_3(q) \begin{pmatrix} \ddot{x} \\ \ddot{y} \end{pmatrix} + \\ + \bar{N}_{1,3}(q, \dot{q}) \dot{q} + \bar{G}_{1,3}(q) = C(q) \begin{pmatrix} \lambda_n \\ \lambda_r \end{pmatrix} + \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} \end{aligned} \quad (6)$$

$$\text{with } M_1 := \begin{pmatrix} m_{11} & m_{13} \\ m_{31} & m_{33} \end{pmatrix} \in \mathbb{R}^2 ; M_2 := \begin{pmatrix} m_{12} & m_{14} \\ m_{32} & m_{34} \end{pmatrix} \in \mathbb{R}^2$$

$$M_3 := \begin{pmatrix} m_{16} & m_{17} \\ m_{36} & m_{37} \end{pmatrix} \in \mathbb{R}^2 ; C(q) := \begin{pmatrix} J_1^T(1,1) & J_1^T(1,2) \\ J_1^T(3,1) & J_1^T(3,2) \end{pmatrix}$$

now if we restrict ourselves to trajectories for which:

- the following angles:

$$\begin{aligned} |\pi - q_{31}| ; |\pi - q_{32}| ; q_{41} ; q_{42} \\ |\pi - (q_{32} + q_{42})| ; |\pi - (q_{31} + q_{41})| \end{aligned} \quad (7)$$

can be considered as 'small angles',

- the amplitudes of the time derivatives of the angles are of the same order of magnitude of the angles themselves,

then it is clear that equation (6) can be greatly simplified by keeping only the first order terms to obtain:

$$\begin{aligned} M_1 \begin{pmatrix} \ddot{q}_{31} \\ \ddot{q}_{32} \end{pmatrix} + M_2 \begin{pmatrix} \ddot{q}_{41} \\ \ddot{q}_{42} \end{pmatrix} + M_3 \begin{pmatrix} \ddot{x} \\ \ddot{y} \end{pmatrix} + G_0 \begin{pmatrix} \pi - q_{31} \\ \pi - q_{32} \\ q_{41} \\ q_{42} \end{pmatrix} = \\ C(q) \begin{pmatrix} \lambda_n \\ \lambda_r \end{pmatrix} + \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} \end{aligned} \quad (8)$$

Note that matrices M_1 , M_2 and M_3 are now constant matrices, there is no more Coriolis term and the gravity term is affine in the directly controlled variables q_{31}, q_{41}, q_{32} and q_{42} with $G_0 := [Diag(-g_{34}, -g_{34}) \quad Diag(g_4, g_4)]$, and $g_{34} := \frac{g}{2} (m_3 l_3 + m_4 (2l_3 + l_4))$; $g_4 = \frac{g}{2} m_4 l_4$

To go further, the approximate expressions of λ_n and λ_r have to be investigated. For that, let us have a look on the x and y equations. Under the above assumptions, the equations for x and y can be written in the following simplified form:

$$m\ddot{x} = \lambda_r - \left(\frac{g_{34}}{g} \quad \frac{g_{34}}{g} \quad \frac{g_4}{g} \quad \frac{g_4}{g} \right) \begin{pmatrix} \ddot{q}_{31} \\ \ddot{q}_{32} \\ \ddot{q}_{41} \\ \ddot{q}_{42} \end{pmatrix} + \left(\frac{1}{2} m_1 l_1 \right) \ddot{q}_1 \quad (9)$$

$$m\ddot{y} = -m g + \lambda_n \quad (10)$$

using equations (9)-(10) to express $C(q) \begin{pmatrix} \lambda_n \\ \lambda_r \end{pmatrix}$ appearing in (8), leads after some manipulations to:

$$\begin{aligned} M_1 \begin{pmatrix} \ddot{q}_{31} \\ \ddot{q}_{32} \end{pmatrix} + M_2 \begin{pmatrix} \ddot{q}_{41} \\ \ddot{q}_{42} \end{pmatrix} - G_2 \begin{pmatrix} \ddot{q}_{31} \\ \ddot{q}_{32} \\ \ddot{q}_{41} \\ \ddot{q}_{42} \end{pmatrix} + (M_3 - M_4) \begin{pmatrix} \ddot{x} \\ \ddot{y} \end{pmatrix} + \\ (G_0 - C_1) \begin{pmatrix} \pi - q_{31} \\ \pi - q_{32} \\ q_{41} \\ q_{42} \end{pmatrix} - \left(\frac{1}{2} m_1 l_1 (l_3 + l_4) \right) \ddot{q}_1 = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} \end{aligned} \quad (11)$$

Now using geometric arguments (first order approximation) to write \ddot{x} and \ddot{y} under swing phase conditions gives:

$$\begin{pmatrix} \ddot{x} \\ \ddot{y} \end{pmatrix} \approx \begin{pmatrix} -(l_3 + l_4) & -l_4 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} \ddot{q}_{31} \\ \ddot{q}_{41} \end{pmatrix} \quad (12)$$

that gives when injected in (11):

$$\begin{aligned} [M_3^* + (M_1 \quad M_2) - G_2] \begin{pmatrix} \ddot{q}_{31} \\ \ddot{q}_{32} \\ \ddot{q}_{41} \\ \ddot{q}_{42} \end{pmatrix} + (G_0 - C_1) \begin{pmatrix} \pi - q_{31} \\ \pi - q_{32} \\ q_{41} \\ q_{42} \end{pmatrix} - \\ \left(\frac{1}{2} m_1 l_1 (l_3 + l_4) \right) \ddot{q}_1 = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} \end{aligned} \quad (13)$$

$$\text{with } M_3^* := (M_3 - M_4) \begin{pmatrix} -(l_3 + l_4) & 0 & -l_4 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}$$

Now, equation (13) may be written in terms of X_c (introduced in section I) and \ddot{X}_c as follows:

$$\begin{aligned} & \left[M_3^* + (M_1 \quad M_2) - G_2 \right] \begin{pmatrix} -\mathbb{I} & 0 \\ 0 & \mathbb{I} \end{pmatrix} \ddot{X}_c + (G_0 - C_1) X_c \\ & - \begin{pmatrix} \frac{1}{2} m_1 l_1 (l_3 + l_4) \\ 0 \end{pmatrix} \ddot{q}_1 = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix} \end{aligned} \quad (14)$$

where \mathbb{I} in (14) represents the identity matrix in $\mathbb{R}^{2 \times 2}$. Finally, by using (14), one may write $u_1 + u_2$ in terms of X_c and its second derivative as:

$$u_1 + u_2 = L_0^* X_c + L_2^* \ddot{X}_c - \frac{1}{2} m_1 l_1 (l_3 + l_4) \ddot{q}_1 \quad (15)$$

where

$$L_0^* = (1 \quad 1) (G_0 - C_1) \quad ; \quad L_2^* = (1 \quad 1) [M_3^* + (M_1 \quad M_2) - G_2] \begin{pmatrix} -\mathbb{I} & 0 \\ 0 & \mathbb{I} \end{pmatrix} \quad (16)$$

This finally gives when used in (5), keeping only first order terms:

$$\left(\frac{1}{4} m_1 l_1^2 + \frac{1}{2} m_1 l_1 (l_3 + l_4) + I_1 \right) \ddot{q}_1 = \frac{1}{2} m_1 l_1 \ddot{x} + \frac{1}{2} m_1 l_1 g q_1 - (L_0^* X_c + L_2^* \ddot{X}_c) \quad (17)$$

According to (12), \ddot{x} can be written as:

$$\ddot{x} = \begin{pmatrix} -(l_3 + l_4) & 0 & -l_4 & 0 \end{pmatrix} \begin{pmatrix} -\mathbb{I} & 0 \\ 0 & \mathbb{I} \end{pmatrix} \ddot{X}_c =: D \ddot{X}_c \quad (18)$$

therefore,

$$\ddot{q}_1 = \frac{\frac{1}{2} m_1 l_1 g}{d} q_1 - \frac{L_0^*}{d} X_c + \frac{\frac{1}{2} m_1 l_1 D - L_2^*}{d} \ddot{X}_c \quad (19)$$

where $d = \frac{1}{4} m_1 l_1^2 + \frac{1}{2} m_1 l_1 (l_3 + l_4) + I_1$. (19) writes:

$$\ddot{q}_1 = a q_1 - L_0 X_c + L_2 \ddot{X}_c \quad (20)$$

A. Generation of reference trajectories for X_c

The reference trajectories of X_c on the time interval $[t_0, t_f]$ are completely parameterized by the boundary conditions $X_c(t_0)$, $\dot{X}_c(t_0)$, $X_c(t_f)$, $\dot{X}_c(t_f)$. For instance, the reference trajectories on each of the scalar variables q_{31} , q_{32} , q_{41} and q_{42} is the unique 3rd order polynomial satisfying the four boundary conditions. This can be written in a compact form as follows:

$$X_c(t) = \Phi(t) \Psi \mathcal{X} \quad (21)$$

$$\mathcal{X} = (X_c(t_0) \quad \dot{X}_c(t_0) \quad X_c(t_f) \quad \dot{X}_c(t_f))^T \in \mathbb{R}^{16} \quad (22)$$

$$\Phi(t) := \begin{pmatrix} \varphi(t) & 0 & 0 & 0 \\ 0 & \varphi(t) & 0 & 0 \\ 0 & 0 & \varphi(t) & 0 \\ 0 & 0 & 0 & \varphi(t) \end{pmatrix} \in \mathbb{R}^{4 \times 16}$$

$$\varphi(t) = (1 \quad t \quad t^2/2 \quad t^3/6)$$

$$\Psi = \begin{pmatrix} \Phi(t_0) \\ \dot{\Phi}(t_0) \\ \Phi(t_f) \\ \dot{\Phi}(t_f) \end{pmatrix}^{-1} \in \mathbb{R}^{16 \times 16}$$

B. Evolution of unactuated coordinate under perfect tracking

Let us assume that the reference trajectories on X_c defined above are perfectly tracked. This is not really a restrictive assumption since X_c is totally controlled by the four control inputs $u \in \mathbb{R}^4$. The only obstacle upon such a perfect tracking comes from either saturations or insufficient contact forces. However, the class of small angles trajectories clearly disposes of such problems. For the time being, let us concentrate on what happens to the torso's angle under perfect tracking. Injecting (21) in (20) gives:

$$\ddot{q}_1 = a q_1 - (L_0 \Phi(t) + L_2 \dot{\Phi}(t)) \Psi \mathcal{X} \quad (23)$$

Let us define the state of the torso by $\Theta := (q_1 \quad \dot{q}_1)^T$, using (23), one may write:

$$\begin{aligned} \dot{\Theta}(t) &= \begin{pmatrix} 0 & 1 \\ a & 0 \end{pmatrix} \Theta(t) + \begin{pmatrix} 0_{1 \times 16} \\ -(L_0 \Phi(t) + L_2 \dot{\Phi}(t)) \Psi \end{pmatrix} \mathcal{X} \\ &=: A \Theta(t) + B(t) \mathcal{X} \end{aligned} \quad (24)$$

Therefore, one clearly has:

$$\Theta(t_f) = \bar{A}(t_0, t_f) \Theta(t_0) + \bar{B}(t_0, t_f) \mathcal{X} \quad (25)$$

$$\bar{A}(t_0, t_f) = \bar{A}(0, t_f - t_0) := \exp[A(t_f - t_0)] \quad (26)$$

$$\bar{B}(t_0, t_f) = \bar{B}(0, t_f - t_0) := \int_{t_0}^{t_f} \exp(A(t_f - \tau)) B(\tau) d\tau \quad (27)$$

C. Recall on impact's dynamics

In this section, the principle of the impact dynamics used in the forthcoming developments is recalled. For that, consider first the expressions of the feet cartesian coordinates $x_{p_i}(q), y_{p_i}(q)$. Let us then define $J_i(q)$ (for $i \in \{1, 2\}$) as follows:

$$J_i(q) := \frac{\partial}{\partial q} \begin{pmatrix} y_{p_i}(q) \\ x_{p_i}(q) \end{pmatrix} \in \mathbb{R}^{2 \times 7} \quad (28)$$

Let us define also (for $i \in \{1, 2\}$) the Lagrange multipliers relative to the contact forces by $\lambda_i = \begin{pmatrix} \lambda_{ni} \\ \lambda_{ti} \end{pmatrix}$ (λ_{ni} : relative to the normal force of the foot i , and λ_{ti} : relative to its tangential force). The single impact dynamics can then be given by:

$$M(q)(\dot{q}^+ - \dot{q}^-) = J_2^T(q) \lambda_2 \quad (29)$$

$$J_2(q) \dot{q}^+ = 0 \quad (30)$$

$$J_1(q) \dot{q}^+ \geq 0 \quad (31)$$

$$\Lambda(\mu_0) \lambda_2 \geq 0 \quad (32)$$

- ✓ Equation (30) states that the formerly swing leg is becoming the new support one, without rebound nor slip at impact.
- ✓ Inequality (31) states that the formerly stance leg is now leaving the ground.
- ✓ Inequality (32) guarantees the classical non penetration and non slipping conditions at the contact point.

✓ The matrix $\Lambda(\mu_0)$ used in the last inequality is given by

$$\Lambda(\mu_0) := \begin{pmatrix} 1 & 0 \\ \mu_0 & 1 \\ \mu_0 & -1 \end{pmatrix} \in \mathbb{R}^{3 \times 2} \quad (33)$$

The solution of (29)-(30) is given by (3). Let:

$$Q_1(q) := \left[I - M^{-1} J_2^T (J_2 M^{-1} J_2^T)^{-1} J_2 \right]$$

$$Q_2(q) = \left[(J_2 M^{-1} J_2^T)^{-1} J_2 \right]$$

$$Q_3(q) = J_1(q) Q_1(q)$$

$$Q_4(q) = \Lambda(\mu_0) Q_2(q)$$

then the single support impact constraints resume to:

$$\dot{q}^+ = Q_1(q) \dot{q}^- \quad (34)$$

$$Q_3(q) \dot{q}^- \geq 0 \quad (35)$$

$$Q_4(q) \dot{q}^- \geq 0 \quad (36)$$

Note that (35)-(36) insure a well-defined single support-type impact, while equation (34) gives the velocities post-impact function of positions and velocities pre-impact.

IV. FEEDBACK DEFINITION

The starting point of the proposed feedback is the torso's dynamic (20). Since $X_c \in \mathbb{R}^4$ is completely controllable via existing actuators, one may legitimately discuss on the basis of the following 10-dimensional controllable system

$$\ddot{q}_1 = a q_1 - L_0 X_c + L_2 v \quad (37)$$

$$\dot{X}_c = v \quad (38)$$

In the following, the choice of the alternative control $v \in \mathbb{R}^4$ will be explained. Equations (37)-(38) can be easily put in a state-space form:

$$\dot{Z} = AZ + Bv \quad (39)$$

$$Z := \begin{pmatrix} q_1 \\ X_c \\ \dot{q}_1 \\ \dot{X}_c \end{pmatrix} \in \mathbb{R}^{10}; A := \begin{pmatrix} 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & \mathbb{I} \\ a & -L_0 & 0 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}; B := \begin{pmatrix} 0 \\ 0 \\ L_2 \\ \mathbb{I} \end{pmatrix} \quad (40)$$

where the 0 elements in (40) are null matrices of suitable dimensions and \mathbb{I} is the identity matrix in $\mathbb{R}^{4 \times 4}$. Since (39) is completely controllable, the only thing to do is to define a final state $Z(t_f)$ that is to be reached at $t = t_f$ together with a transient quadratic cost function to be minimized.

Consider the following notations:

$$Z = \begin{pmatrix} Z_1 \\ Z_2 \end{pmatrix}; Z_1 := \begin{pmatrix} q_1 \\ X_c \end{pmatrix} \in \mathbb{R}^5; Z_2 := \begin{pmatrix} \dot{q}_1 \\ \dot{X}_c \end{pmatrix} \in \mathbb{R}^5 \quad (41)$$

Let $q = K(Z_1)$ be the function that gives q under swing phase assumption on the feet 1, let us also define $K'(Z_1) := \frac{\partial K}{\partial Z_1}(Z_1)$. Finally for all $q \in \mathbb{R}^7$, $\Pi_i q$ refers to the i^{th} component of q . The final state $Z^f = (Z_1^{fT} Z_2^{fT})^T$ is therefore defined as follows:

- 1) First, the position vector Z_1^f is a priori given. it must reflect the desired mean velocity of the walk. Furthermore, it must respect the basic "small angle" assumption. All the following rules aim to define Z_2^f .
- 2) The torso's angular velocity just after the impact must be 0:

$$\left[\Pi_5 Q_1(K(Z_1^f)) K'(Z_1^f) \right] Z_2^f = 0 \quad (42)$$

- 3) The horizontal hip's velocity \dot{x} **just after** the impact must be equal to v^r , this can be written as follows:

$$\left[\Pi_6 Q_1(K(Z_1^f)) K'(Z_1^f) \right] Z_2^f = v^r \quad (43)$$

- 4) The vertical hip's velocity \dot{y} **just after** the impact must be equal to 0, this can be written as follows

$$\left[\Pi_7 Q_1(K(Z_1^f)) K'(Z_1^f) \right] Z_2^f = 0 \quad (44)$$

- 5) The vertical velocity of the free foot **just before** the impact must be equal to some $v^p < 0$ while its horizontal velocity must be 0, that is:

$$\left[J_2(K(Z_1^f)) K'(Z_1^f) \right] Z_2^f = \begin{pmatrix} v^p \\ 0 \end{pmatrix} \quad (45)$$

- 6) The impact inequalities (35)-(36) must be satisfied:

$$\left[Q_3(K(Z_1^f)) K'(Z_1^f) \right] Z_2^f \geq 0 \quad (46)$$

$$\left[Q_4(K(Z_1^f)) K'(Z_1^f) \right] Z_2^f \geq 0 \quad (47)$$

- 7) The final constraint concerns the contact conditions on the trajectory joining the final state Z^f . To express this condition, note that under the "small angles" assumption, equations (9)-(10) together with (18) can be invoked to argue that $\lambda_n \geq 0$ is obviously satisfied and that the condition $|\lambda_r| \leq \mu_0 \lambda_n$ resumes to:

$$-\alpha \mu_0 m g \leq \bar{D} v \leq \alpha \mu_0 m g \quad (48)$$

where

$$\bar{D} = \left[\begin{pmatrix} \frac{g_{34}}{g} & \frac{g_{34}}{g} & \frac{g_4}{g} & \frac{g_4}{g} \end{pmatrix} \begin{pmatrix} -\mathbb{I} & 0 \\ 0 & \mathbb{I} \end{pmatrix} - m D \right] \quad (49)$$

$\alpha \in]0, 1[$ is a security margin. Note that (48) is a saturation condition on the control v of the system (39) under interest.

These constraints can be summarized in:

$$A_{eq}(Z_1^f) Z_2^f = b_{eq}(v_r, v_p); A_{ineq}(Z_1^f) Z_2^f \geq 0; A_s v \leq b_s \quad (50)$$

V. NUMERICAL SIMULATIONS

$$A_{eq}(Z_1^f) := \begin{pmatrix} \Pi_5 Q_1(K(Z_1^f))K'(Z_1^f) \\ \Pi_6 Q_1(K(Z_1^f))K'(Z_1^f) \\ \Pi_7 Q_1(K(Z_1^f))K'(Z_1^f) \\ J_2(K(Z_1^f)) \end{pmatrix} \in \mathbb{R}^{5 \times 5} \quad ; \quad b_s = \alpha \mu_0 m g \begin{pmatrix} 1 \\ 1 \end{pmatrix}$$

$$b_{eq}(v_r, v_p) := \begin{pmatrix} 0 \\ v^r \\ 0 \\ v^p \\ 0 \end{pmatrix} \quad ; \quad A_{ineq}(Z_1^f) := \begin{pmatrix} Q_3(K(Z_1^f))K'(Z_1^f) \\ Q_4(K(Z_1^f))K'(Z_1^f) \end{pmatrix} \quad ; \quad A_s := \begin{pmatrix} \bar{D} \\ -\bar{D} \end{pmatrix}$$

Therefore, the desired final state Z_f is now uniquely determined by the choice of Z_1^f as follows

$$\hat{Z}(Z_1^f) := \begin{pmatrix} Z_1^f \\ \hat{Z}_2^f(Z_1^f, v_r, v_p) \end{pmatrix} \quad (51)$$

where \hat{Z}_2^f is solution of the following linearly constrained quadratic optimization problem:

$$\hat{Z}_2^f(Z_1^f, v_r, v_p) := \text{Arg} \min_{Z_2^f \in \mathcal{Z}} \left\{ \|A_{eq}(Z_1^f)Z_2^f - b_{eq}(v_r, v_p)\|^2 \quad \text{under} \quad A_{ineq}(Z_1^f)Z_2^f \geq 0 \right\} \quad (52)$$

where $\mathcal{Z} \subset \mathbb{R}^5$ is the set of admissible values reflecting the "small angles" assumption.

With the final state Z^f in hand, the problem is now to define a state feedback to be applied during the step over the interval $[0, t_f]$ so that $Z(t_f) = Z^f$. For, let us give some useful notations

- Assume that a discret-time scheme is used with a sampling time of $\tau > 0$.
- Let Φ_i and Ψ_i be the i -steps discrete transition matrices for the linear system (39), namely

$$Z(i\tau) = \Phi_i Z(0) + \Psi_i \tilde{v} \quad ; \quad \tilde{v} \in \mathbb{R}^{4 \times i} \quad (53)$$

- The walking step duration t_f is a multiple of the sampling time τ , namely $t_f = N \cdot \tau$.

Since a finite time response is required (for Z to reach Z^f), time-varying feedback control is necessary. For that, let $k \in \{0, 1, \dots, N-1\}$ represent the discrete time counter during the walking step time-interval. Therefore, at each sampling instant $k \in \{0, 1, \dots, N-1\}$ one has to solve the following linearly constrained quadratic problem:

$$\hat{v}(k, Z(k), Z^f) := \text{Arg} \min_{\tilde{v} \in \mathbb{R}^{4(N-k)}} \left\| \Psi_{N-k} \tilde{v} + \Phi_{N-k} Z(k) - Z^f \right\|^2 \quad (54)$$

under $\tilde{A}_s \tilde{v} \leq \tilde{b}_s$

$$\tilde{A}_s := \begin{pmatrix} A_s & 0 & \dots & 0 & 0 \\ 0 & A_s & 0 & \dots & 0 \\ \dots & \dots & \dots & \dots & \dots \\ \dots & \dots & \dots & \dots & \dots \\ 0 & 0 & \dots & 0 & A_s \end{pmatrix} \in \mathbb{R}^{2(N-k) \times 4(N-k)}$$

$$\tilde{b}_s := \begin{pmatrix} b_s \\ \vdots \\ b_s \end{pmatrix} \in \mathbb{R}^{2(N-k)}$$

The objective of this simulation scenario is the application of the proposed strategy to control the biped robot RABBIT for a dynamic walking gait starting from rest. The walking-step duration is $t_f = 1.2 \text{ sec}$, the desired foot pre-impact velocity is $v_p = -0.07 \text{ m/sec}$. Initial condition on the unactuated coordinate is $(q_1, \dot{q}_1)_0 = (0, 6^\circ)$, the sampling time is $\tau = 0.05 \text{ sec}$, and the mean walking velocity is $v_r = -0.132 \text{ m/sec}$. The obtained simulation results are plotted in figures 3-7. Figure 3 displays the evolution of the articular positions and velocities of the robot's femurs versus time. Figure 4 depicts the evolution of the articular positions and velocities of the robot's tibias versus time. From these figures concerning the actuated coordinates (direct controlled variables) of the robot, it can be seen clearly the convergence to a cyclic walking gait. The evolution of the unactuated coordinate is plotted in figure 5 which represents the articular position and velocity of the torso versus time, where it can also be seen the convergence a cyclic trajectory. Figure 6 shows the evolution of the y-cartesian hip's trajectories versus time. The control inputs, are depicted in figure 7, showing the torques to be generated by the actuators.

VI. CONCLUSION

In this paper a discret-time control strategy is proposed to control a five-link four-actuator biped walking robot. The proposed control strategy consists in a choice of a particular configurations that enables a full state controllability avoiding the need to use Poincaré-like argumentation in the proof of convergence to stable cyclic walking gaits. The basic idea relies in considering small angles, which enables us to express the dynamics of the indirectly controlled variable (unactuated coordinate) as linear function of the directly controlled variables (actuated coordinates) and their derivatives. Then a discrete-time feedback is proposed to control the whole system in the aim to reproduce a cyclic walking gait. A demonstration movie accompanying the paper shows the obtained walking gait.
