Entities, Names and Surrogates

A KR Viewpoint on a Real Example

(joint work with Michel Leclère)
Agenda

- Identification problems in CS
  - In databases
  - On the web
  - Features concerning id pbs
- Current solutions
  - Removing the problem
  - Similarity measures
  - Logical approach
- Identification pbs in digital libraries
  - Authority linking
  - Current approaches
  - Knowledge approach
Identification problems in databases

Record linkage

“The term record linkage has been used to indicate the bringing together of two or more separately recorded pieces of information concerning a particular individual or family.”

Study on family fertility in relation to the presence of hereditary disease

Linking birth records to marriage records
Record Linkage
Identification problems in databases

Two records must have sufficiently comparable information for making decisions about whether the records represent the same entity

**Difficulties**

Come from the unreliability of the identifying information contained in records which concern the same entity

**Solution**

When two records have missing or contradictory information, then the records can only be correctly matched if additional information is obtained
Identification problems in databases

Entity resolution, Reference reconciliation: which records represent the same entity, identifying multiple refs to the same object and distinguishing them from mentions of different objects

de-duplication, duplicate data (object) is deleted

Classical problem: creation of mailing lists

merging records judged to represent the same world entity

record linkage, linking records through refs to same world entities

Object identification: To single out, to distinguish, to recognize
Referent

Reference Reconciliation
Deduplicate
referent

Merge/Purge
Record Linkage
Identification problems on the web

Uniform Resource Identifiers = global identifiers of web resources, a cornerstone of Web architecture, providing identification that is common across the Web.

The global scope of URIs promotes large-scale "network effects": a resource with an associated URI allows another party to create a link to it, make or refute assertions about it, retrieve or cache a representation of it, include all or part of it by reference into another representation, annotate it, ...
Identification problems on the web

**Search the web** centered on **individuals**

e.g., the various facts concerning a person if brought together form an extensively documented history of his life ...

The knowledge represented in the web is gathered and entities are identified by a multitude of persons and processes for many different purposes, from many different sources.

⇒ **inconsistencies** occur within and between the data gathered by different processes.

“Identifying equivalent entities is a serious business”
Collective Entity Resolution

(people, organization)
Is (the person) A within the organization B the same as A (or A') within C?
(people, people, document)
is coauthors A and B of C the same as A and B of D?”

Paul and Jane are co-authors, Jane is identified
Paul = Paul1 or Paul2?

Paul and Mary are co-authors, Mary is identified
furthermore Paul1 and Jane and Mary are co-authors
then it is possible that Paul is Paul1 in the three cases
Identification problems **Features**

- Natural language pbs (e.g., word sense disambiguation, generating referring expressions, web crawling) versus more or less controlled and structured information
- References may have different amount of information associated with them (e.g., an authority-person in a digital library is not a biographical record)
- Quality and amount of data
- Distinction « primary information » and « derived information » computed on a network
- Metadata (more or less structured, semantic web, digital libraries)
- PIM – personal information management: examines data from several heterogeneous sources on the desktop (files, mails, ...), extract instances of different classes: Person, Message, Paper, ... and relationships between instances: sender, author, ...
“There is no single paradigmatic author name disambiguation task – each bibliographic database, each digital library, and each collection of publications has its own unique set of problems and issues.”

Databases differ in size, data quality, author diversity, types of metadata, rate of growth of new items, cultural context of how the data are used ...

“For certain purposes (e.g., awarding the Nobel Prize to the author of a breakthrough), it may be very important to achieve a high accuracy of disambiguation. For other purposes (e.g., as an aid to routine information retrieval), it may suffice to assign a high proportion of a person’s articles correctly, with little penalty occurring if some articles are missed or mis-assigned.” (N.R. Smalheiser, V.I. Torvik)
Removing pb

**Unique Name Assumption**

In databases

specializations of FOL: no function symbols and « ... the two other fundamental specializations are the focus on finite models and the special use of constant symbols... for distinct constants c and c’, all interpretations that are considered satisfy neg(c=c’).” » (Abiteboul, Hull, Vianu)

In knowledge representation

Description Logics « The semantics maps each individual name a to an element aᵢ in Dᵢ. We assume that distinct individual names denote distinct objects. Therefore, this mapping has to respect the unique name assumption (UNA), that is, if a, b are distinct names, then aᵢ ≠ bᵢ.” (The Description Logic Handbook)
It is possible to create a unique identifier for an entity in a given domain, and that identifier would have only local significance to the creator. Anything attempting to gather data on that resource, from a foreign application, or with reference to another knowledge source would have to resolve it against existing references.

impossible in some situations!
Current solution Classification

An entity is described by a set (or vector) of attributes
attribute values are simple datatypes (e.g., strings or numbers)
approximate similarity measures for each kind of attributes
vector similarity measure
weighted combination of the similarities

Ex. Graph of similarity scores for a PIM (Personal Information Management) tool
Current solution **Graph of Similarity Scores**

**Principles**

Dependency graph: two kinds of node. Pair of references \((r, r')\) (which potentially refer to the same real-world entity) and pair of attribute values \((a, a')\), \(a\) of \(r\), \(a'\) of \(r'\). Each node has a similarity score. Arc from \((a, a')\) to \((r, r')\) if the similarity (reconciliation) of \(r\) and \(r'\) depends on the similarity (recon.) of \((r, r')\)

Propagation of the similarity scores from node to node in the graph

Enriching the references after merging \(r\) and \(r'\) all the attributes of \(r\) can also be considered as attributes of \(r'\)

Enforcing constraints e.g. the authors of the same paper are distinct from each other (some node are marked *non_merge*)
Current solution Logical approach

Data sources S1 and S2 conforming to the same schema

\textit{Reconcile}(a,b) \text{ iff } a \text{ and } b \text{ refer to the same world entity}

\neg \text{Reconcile}(a,b) \text{ iff they don’t}

A method is \textit{complete} \text{ iff} for each pair \((a,b)\), \(a\) in S1, \(b\) in S2
\text{Reconcile}(a,b) \text{ or } \neg \text{Reconcile}(a,b)
Current solution Logical approach

Rules

- S1 UNA \( S1(x) \land S1(y) \land (x \neq y) \rightarrow \neg \text{Reconcile}(x,y) \)
- S1(x) \land S2(y) \land \text{Reconcile}(x,y) \land S1(z) \rightarrow \neg \text{Reconcile}(z,y) 
- LUNA for the relation R: \( R(z,x) \land R(z,y) \land (x \neq y) \rightarrow \neg \text{Reconcile}(x,y) \)
  \( R(x,z) \land R(y,z) \land (x \neq y) \rightarrow \neg \text{Reconcile}(x,y) \)
- Disjunction of classes C and D: \( C(x) \land D(y) \rightarrow \neg \text{Reconcile}(x,y) \)
- Functionality of R: \( \text{Reconcile}(x,y) \land R(x,z) \land R(y,w) \rightarrow \text{Reconcile}(z,w) \)
- etc

Reasoning: all \( \text{Reconcile}(x,y) \) and all \( \neg \text{Reconcile}(x,y) \)
deduced from Facts + Rules
“Individual markers serve as surrogates that uniquely identify the individuals that are cataloged in a conceptual system ... names are demoted to the status of characteristics that are no more fundamental than weight or hair color (since one entity may have multiple names or aliases, and multiple entities may have the same name).”

“Since surrogates are unique only within a particular computer system, communication between system still depends on printable names with their potential ambiguities.”

“There are no URLs for things that cannot be flattened out and stored on a computer disk, such as dogs, trees, and people. For such things, the surrogates serve as local substitutes within a database. But the task of matching the surrogates to the physical objects cannot be done wholly within a computer or even a network of computers. There must some sense organs –human or robotic- that can relate the internal identifiers to the physical world.”

(Sowa)
Digital Libraries
Bases of notices
Notice = metadata
Bibliographic notices: metadata associated with a document
Authority notices: metadata associated with instances of specific classes (Person, Collectivity, Geo_place, Subject, ...)
Each notice has an identifier: surrogate
Relationships between bibliographic notices and authority notices (authorOf, editorOf, ...) are values of attributes

The set of metadata bases can be seen as a structured graph
Dynamic

Adding notices to a base
Merging bibliographic bases
Making data accessible to outside

Quality of the bases of notices
Consistency inside and between bases
Relevance of the subject
Maintenance of the different bases
Goal: building a service of authority identification
Identifying in a new notice references to an entity co-referent with an authority (person, collectivity, subject) in a bibliographic notice
Manual linking

- Given a « term » and an « authority type », e.g. (« Victor Hugo », Person) search the person authority file containing « Victor Hugo » as a normalized or a rejected form
- Authority notices are returned to the user
- The user assigns the more relevant authority to the term (links the term to the identifier) or create a new authority

Automatic linking by similarity scores

- Similarity score for each attribute of the authority that is present with « term »
- Aggregation of similarity scores
- Authorities ranked by decreasing score, the first is considered if there is a gap with the second
Exploitation of the information in the network of notices

- Representation of the database in GBKR (our CG model)
- Enrichment of the authority notices
- Identification of authorities in a new notice
• FRBRoo 1.0 (2009)
  « a formal ontology intended to capture and represent the underlying semantics of bibliographic information and to facilitate the integration, mediation, and interchange of bibliographic and museum information »
  Hierarchy of classes (Work, Expression, Manifestation, ...), hierarchy of relations with signature (brought_into_life (Birth, Person), has_fragment(Expression_fragment, Expression), ...

• Representation in RDFS then in a GBKR vocabulary
• Features :
  – Properties and subproperties of FRBRoo represented as ordered relations
  – Distinction between concept and data
  • A title vs. a string on the cover
  – Metadata concerning the notices (date, origine, sources...)
Knowledge approach 1

Authority Identification

Selection pattern: necessary and optional information

Querying the enriched notice base
- Necessary information: filter
- Optional information: ranking

Collective consistency checking
Identification Selection pattern

Selection pattern: a query in information retrieval

Necessary Part strong matching with enriched authority notice

Used to select a set of candidate authorities

Optional Part used to rank the candidate authorities

Example: pattern for person

- familyName
- firstName
- lifeDate
- domOfInterest
- lang
- role
- normform

Person

manifestation

Lang

Topic
Identification A new bib notice

Identification **Answers**

A set of authorities

![Diagram showing relationships between Manifestation, Person, Thesis, and Topic nodes with various attributes such as `famName`, `firstName`, `normform`, `lang`, `domofint`, `rejectedform`, and `Lang` for `fre`. The diagram includes nodes for «Bernard», «Christian», «Bernard, Christian», «Hépatites», «Hépatite», «Foie -- Inflammation», «Intelligence artificielle», and «Machines Intelligentes». Notice: 36 and Notice: 55 are also indicated.]
The optional part is used as a ranking criteria for the selected authorities

Complexity of the transformations of the enriched authority needed to obtain a hom from the optional part to the authority
Collective consistency checking

Constraints on relations between authorities

For an article in a journal, the publication date should be consistent with the lifedate of the author

For a thesis the domains of interest of the director and of the author should intersect

For a paper with several authors, attributes associated with co-authors of a document should respect some constraints such as lifedates, domains of interest, languages, ...

Ex. A paper written by Jean Petit and Christian Bernard

«Jean Petit», ordered authorities [a11, a41, a35]
«Christian Bernard», ordered authorities [a55, a36]

If (a11,a55) and (a41,a55) and (a41,a36) are inconsistent co-authors Return
(«Jean Petit»,«Christian Bernard»), [(a11, a36),(a35,a55),(a35,a36)]
Perspective 1  Work in progress

All notions are available in GBKR (cogui and cogitant)

• **Knowledge representation**: enrichment rules, selection pattern for each sort of authority, constraints, approximate hom and ranking

• **Experiments**: checking the methodology, the knowledge, the whole graph

• **Mapping**: other ontologies (for integrating notices coming from other sources)

• **Introduction** of the authority identification service as a tool

• **Quality of data**: de-duplication, errors in links
Perspective 2  Relationships with logic

Classical FOL
  two distinct constants can have the same interpretation

KIF has two kinds of constants: for one kind, uniqueness is assumed; for the other kind, either \( a = b \) or \( a \neq b \) is possible.

Standard names
  surrogates and ordinary constants, the interpretation domain is the set of surrogates

Surrogates, ordinary constants and litterals with different boolean match predicates for different types of litterals (e.g., match_string, match_date, match_name), the interpretation domain contains the set of surrogates.
A « killing » application?
Large amount of metadata built on standard Ontologies by professionals
The web is not a digital library ...
A first step before attacking part of the web?
« Pour le dire vite, le web sémantique est la revanche des métadonnées sur l'utopie du Full Text. C'est donc aussi une affaire de bibliothécaires. »
Yann Nicolas

A very sensitive issue
« However, some record linkage projects (e.g., involving sensitive data on health, finance, and crime) have met with public outcries because they were perceived as secret, revealing, without-consent, inaccurate, or resulted in administrative action (U.S. General Accountability Office, 2001). Thus, it is important to keep the public in mind when embarking on an author disambiguation project. At the very least, author disambiguation research should be transparent. »
Everything You Always Wanted to Know About ...

M. Chein (LIRMM) ICCS 2010
'What is in a name? Very much if the wit of man could find it out.' Whoever penned this well known saying undoubtedly had it each with a history behind it.
