## Abstract

We consider the entailment problem in the fragment of first-order logic (FOL) composed of existentially closed conjunctions of literals (without functions), denoted  $\text{FOL}(\exists, \wedge, \neg_a)$ . This problem can be recast as several fundamental problems in artificial intelligence and databases, namely query containment for conjunctive queries with negation, clause entailment for clauses without functions and query answering with incomplete information for Boolean conjunctive queries with negation over a fact base. Entailment in  $\text{FOL}(\exists, \wedge, \neg_a)$  is  $\Pi_2^P$ -complete, whereas it is only NP-complete when the formulas contain no negation. We investigate the role of specific literals in this complexity increase. These literals have the property of being “exchangeable”, with this notion taking the structure of the formulas into account. To focus on the structure of formulas, we shall see them as labeled graphs. Graph homomorphism, which provides a sound and complete proof procedure for positive formulas, is at the core of this study. Let  $\text{ENTAILMENT}_k$  be the following family of problems: given two formulas  $g$  and  $h$  in  $\text{FOL}(\exists, \wedge, \neg_a)$ , such that  $g$  has at most  $k$  pairs of exchangeable literals, is  $g$  entailed by  $h$ ? The main results are that  $\text{ENTAILMENT}_k$  is NP-complete if  $k$  is less or equal to 1, and  $P_{||}^{NP}$ -complete for any value of  $k$  greater or equal to 3. As a corollary of our

proofs, we are able to classify exactly  $\text{ENTAILMENT}_k$  for any value of  $k \neq 2$  when  $g$  is decomposable into a tree.

**Keywords:** Complexity, first-order logic, entailment, negation, graph, homomorphism, query containment, clause implication, conceptual graph.

## 1 Introduction

In this paper, we study the complexity of checking entailment in the fragment of first-order logic (FOL), composed of existentially closed conjunctions of literals. Literals may contain constants but no other function symbols.  $\text{FOL}(\exists, \wedge, \neg_a)$  denotes this fragment (where  $\neg_a$  stands for atomic negation, i.e., negation whose scope is an atom), and  $\text{FOL}(\exists, \wedge)$  is the subfragment with positive literals only. The  $\text{ENTAILMENT}$  problem in a given fragment takes two formulas  $g$  and  $h$  of this fragment as input, and asks if  $g$  is entailed by  $h$ .

**Equivalent problems.**  $\text{FOL}(\exists, \wedge, \neg_a)$ -ENTAILMENT can be seen as a representative of several fundamental problems in artificial intelligence and databases. It can be immediately recast as a *query containment* checking problem, which is one of the fundamental problems in databases. This problem takes two queries  $q_1$  and  $q_2$  as input, and asks if  $q_1$  is contained in  $q_2$ , i.e., if the set of answers to  $q_1$  is included in the set of answers to  $q_2$  for all databases (e.g. [AHV95]). Algorithms based on query containment can be used to solve various problems, such as query evaluation and optimization [CM77, ASU79], rewriting queries using views [Hal01], detecting independence of queries from database updates [LS93], etc. The so-called (positive) *conjunctive queries* form a class of natural and frequently used queries and are considered as the basic database queries [CM77, Ull89]. Their expressive power is equivalent to the select-join-project queries of relational algebra and to non-recursive Datalog rules. Conjunctive queries with negation extend this class with negation on atoms. Query containment checking for conjunctive queries with negation (resp. positive conjunctive queries) is essentially the same problem as  $\text{FOL}(\exists, \wedge, \neg_a)$ -ENTAILMENT (resp.  $\text{FOL}(\exists, \wedge)$ -ENTAILMENT), in the sense that there is a natural bijection from the set of conjunctive queries with negation (resp. positive conjunctive queries) on a given database schema to the set of  $\text{FOL}(\exists, \wedge, \neg_a)$  (resp.  $\text{FOL}(\exists, \wedge)$ ) formulas on the logical language corresponding to this schema, such that query containment coincides with logical entailment. Another related problem in artificial intelligence is the *clause entailment* problem, a basic problem in inductive logic programming [MR94]: given two clauses  $C_1$  and  $C_2$ , does  $C_1$  entail  $C_2$ ? If we consider first-order clauses, i.e., universally closed disjunctions of literals, without function symbols, by contraposition, we obtain an instance of  $\text{FOL}(\exists, \wedge, \neg_a)$ -ENTAILMENT. Let us now look at this from a knowledge representation perspective. A key problem is *query answering*, which, generally speaking, takes a knowledge base and a query as input and asks for the set of answers to the query that can be retrieved from the knowledge base. When the query is a Boolean query, i.e., with a yes/no answer, the problem can be recast as checking whether the query is entailed by the knowledge base. In the case where the knowledge base is simply composed of a set of positive and negative facts, i.e., ground literals or existentially closed conjunctions of literals<sup>1</sup>, and the query is a Boolean conjunctive query with negation, we obtain  $\text{FOL}(\exists, \wedge, \neg_a)$ -ENTAILMENT. Let us point out that this definition of the query answering problem is consistent with the so-called open-world assumption (OWA),

---

<sup>1</sup>In the literature, a fact is usually assumed to be a ground literal. By extending this notion to existentially closed conjunctions of literals, we naturally cover languages such as the basic semantic web language RDF [W3C04], dedicated to the description of web resources, where the so-called “blank nodes” are logically translated into existential variables, or fragments of conceptual graphs (see hereafter). This extension has no incidence on the complexity of the problems we consider.

which assumes incomplete knowledge about the represented world. This assumption is commonly made in knowledge representation and reasoning. The opposite assumption, closed-world assumption (CWA), commonly made in databases, assumes complete knowledge about the represented world. It follows that only positive facts (the data) need to be encoded, with negative facts being obtained by difference with the content of the fact base. Then, negation occurs only in queries and is interpreted as the absence of a positive fact, i.e.,  $\neg p(a_1 \dots a_l)$  holds if  $p(a_1 \dots a_l)$  is *not* entailed by the fact base (while with OWA  $\neg p(a_1 \dots a_l)$  holds if it is entailed by the fact base). Note however that the query containment problem for conjunctive queries with negation is the same regardless of the assumption made (e.g. [LM07]).

Finally, even if this aspect is out of the scope of the present paper, let us mention that a partial order on predicates, or more generally a preorder, can be taken into account without increasing complexity. This allows to represent a terminology where concepts and relations are preordered by a subsumption relation. These concepts and relations are logically translated into a set of predicates used to build facts. We then obtain  $\text{FOL}(\exists, \wedge, \neg_a)$ -ENTAILMENT extended to preordered predicates, which is exactly the entailment problem in a fragment of conceptual graphs, called *polarized conceptual graphs* [Ker01][ML07].

**Complexity and “exchangeable” literals.** Whereas  $\text{FOL}(\exists, \wedge)$ -ENTAILMENT is “only” NP-complete,  $\text{FOL}(\exists, \wedge, \neg_a)$ -ENTAILMENT is  $\Pi_2^P$ -complete<sup>2</sup> [FNTU07] [Mug07]. Some specific cases where  $\text{FOL}(\exists, \wedge, \neg_a)$ -ENTAILMENT has a lower complexity are known but they enforce strong restrictions on the problem instances: briefly said, if  $g$  does not contain any pair of opposite and unifiable literals<sup>3</sup>, then  $\text{FOL}(\exists, \wedge, \neg_a)$ -ENTAILMENT becomes NP-complete (see Section 6). The aim of this paper is to investigate the complexity gap between entailment checking in  $\text{FOL}(\exists, \wedge)$  and  $\text{FOL}(\exists, \wedge, \neg_a)$ . For that, we study the role of specific pairs of literals in the complexity increase. These literals have the property of being “exchangeable”, with this notion being relative not only to the literals themselves, but also to the structure of both formulas. We show that these literals are indeed responsible for the complexity increase, in the sense that if the number of exchangeable literals in  $g$  is *bounded*, then the complexity falls into lower classes of the polynomial hierarchy. The complexity results proven in this paper generalize the results obtained in the various variants of the problem (for instance the query inclusion problem or the clause implication problem).

---

<sup>2</sup> $\Pi_2^P$  is *co*-( $NP^{NP}$ ).

<sup>3</sup>i.e., of the form  $p(u)$  and  $\neg p(v)$ , where  $p(u)$  and  $p(v)$  are unifiable.

$$\exists x \exists y \exists z (s(x, y) \wedge s(y, z) \wedge s(z, x) \wedge \neg s(x, z) \wedge \neg r(y, z, a))$$

Figure 1: A polarized graph

**Graph Tools.** We shall see formulas as labeled graphs to focus on their structure and rely on graph notions like paths, connectivity or cyclicity. These graphs are called polarized graphs (PGs) (name borrowed from [Ker01] in the context of conceptual graphs). More specifically, a  $\text{FOL}(\exists, \wedge, \neg_a)$  formula is represented as a bipartite graph with two kinds of nodes: relation nodes and term nodes. Each term of the formula becomes a term node, labeled  $*$  if it is a variable, otherwise by the constant itself. A positive (resp. negative) literal with predicate symbol  $r$  becomes a relation node labeled  $+r$  (resp.  $-r$ ) and it is linked to the nodes assigned to its terms. The numbers on edges correspond to the position of each term in the literal. See Figure 1 for an example. In the sequel of this section, formulas are denoted by small letters ( $g$  and  $h$ ) and the associated graphs by the corresponding capital letters ( $G$  and  $H$ ).

Homomorphism is a core notion in this study. Basically, a homomorphism from an algebraic structure to another maps the elements of the first structure to elements of the second structure while preserving the relations between elements. A homomorphism  $\pi$  from a graph  $G$  to a graph  $H$  is a mapping from nodes of  $G$  to nodes of  $H$ , which preserves edges, i.e., if  $xy$  is an edge of  $G$  then  $\pi(x)\pi(y)$  is an edge of  $H$ . Since polarized graphs are labeled, there are additional conditions on labels: a relation node is mapped to a node with the same label; a term node can be mapped to any term node if it is labeled  $*$ , otherwise it is mapped to a node with the same constant. Numbers on edges are preserved. Let us point out that, given two formulas  $g$  and  $h$  in  $\text{FOL}(\exists, \wedge, \neg_a)$ , one can identify the notions of a *substitution*  $\sigma$  for variables in  $g$ , s.t. the literals of  $\sigma(g)$  are contained in  $h$ , and a PG homomorphism from  $G$  to  $H$ .  $\text{FOL}(\exists, \wedge)$ -ENTAILMENT can be solved by such a substitution check, or equivalently by a homomorphism check on the PGs assigned to the formulas. This homomorphism check still provides a sound

procedure for entailment in  $\text{FOL}(\exists, \wedge, \neg_a)$ , i.e., the existence of a homomorphism from  $G$  to  $H$  implies that  $g$  is entailed by  $h$ , but of course it is no longer complete, i.e.,  $g$  may be entailed by  $h$  even if there is no homomorphism from  $G$  to  $H$ .

$\text{FOL}(\exists, \wedge, \neg_a)$ -ENTAILMENT can be recast as a problem on PGs involving a number of homomorphism checks exponential in the size of  $H$ . Indeed, negation introduces disguised disjunctive information that cannot be taken into account by homomorphism. This disjunctive information is related to the law of the excluded-middle which holds in classical logic, i.e., for any formula  $A$ ,  $(A \vee \neg A)$  is valid. This leads to reasoning by cases: if nothing is known about  $p(u)$ , then either  $p(u)$  or  $\neg p(u)$  holds. We are thus led to consider all possible ways of “completing”  $H$  with missing relation nodes (while keeping it consistent) and to check if  $G$  can be mapped by homomorphism to all these completions of  $H$ . Intuitively, exchangeable literals are literals from  $G$  that may lead to use the law of the excluded-middle. More precisely, exchangeable literals are literals of the form  $p(u)$  and  $\neg p(v)$  respectively, such that  $u$  and  $v$  can be mapped “at the same place” by homomorphisms from  $G$  to (necessarily distinct) completions of  $H$ .

Finally, let us come back to query answering and the distinction between OWA and CWA. With CWA,  $H$  can be seen as implicitly completed with solely negative relation nodes; then,  $G$  is CWA-entailed by  $H$  if and only if there is a homomorphism from  $G$  to this negative completion of  $H$  (which can be checked without effectively computing this completion). It follows that, with CWA, answering a conjunctive query with negation is not more complex than answering a positive conjunctive query.

**Contributions of the paper.** The results achieved in this paper can be summarized as follows. Please note that we make the assumption that the arity of predicates is bounded by a constant. This assumption is often made in knowledge representation. We first point out that if  $g$  has *no* pair of exchangeable literals, then  $\text{FOL}(\exists, \wedge, \neg_a)$ -ENTAILMENT has the same complexity as in the positive fragment (indeed it can be computed by a homomorphism check, thus is NP-complete). It is then proven that the problem remains NP-complete if  $g$  has *one* pair of exchangeable literals. A natural question that arises is whether the complexity of entailment checking decreases when  $g$  has a *bounded* number of exchangeable literals. Let  $\text{ENTAILMENT}_k$  be the following family of problems: given two formulas  $g$  and  $h$  in  $\text{FOL}(\exists, \wedge, \neg_a)$ , such that  $g$  has at most  $k$  pairs of exchangeable literals, is  $g$  entailed by  $h$ ? It is proven that, for any  $k \geq 3$ ,  $\text{ENTAILMENT}_k$  is  $P_{\parallel}^{\text{NP}}$ -complete. When  $g$  represents a query and  $h$  a base of facts, criteria that decrease the complexity and depend on  $g$  rather than  $h$  are specially relevant, because the query can be considered as small with respect to the fact base, and has generally a simple struc-

Number of exchangeable pairs in $g$	General $g$ and $h$	Homomorphism check polynomial
<b>unbounded</b>	$\Pi_2^P$ -complete (*)	co-NP-complete
0	NP-complete	P
1 (**)	NP-complete	P
<b>bounded by <math>k \geq 3</math></b>	$P_{  }^{NP}$ -complete	co-NP-complete

(\*) already proven ([FNTU07], [Mug07])

(\*\*) the same complexity holds if  $g$  has an unbounded number of exchangeable pairs that all have the same positive (resp. negative) literal

Table 1: Main complexity results

ture (while one cannot expect the fact base to have a special structure). Of course, these criteria are also relevant when  $g$  and  $h$  are both queries. In particular, when  $g$  has a structure decomposable into a tree (we will precise this point later), then checking if there is a homomorphism from  $g$  to  $h$  can be done in polynomial time. In this case, we point out that  $\text{FOL}(\exists, \wedge, \neg_a)$ -ENTAILMENT is co-NP-complete; moreover, a corollary of previous proofs is that  $\text{ENTAILMENT}_k$  remains co-NP-complete for any  $k \geq 3$  and is in P if  $k \leq 1$ .

Table 1 summarizes the complexity results. The recognition problem associated with  $\text{ENTAILMENT}_k$ , i.e., whether  $g$  possesses at most  $k$  pairs of exchangeable literals, is co-NP-complete for any  $k \geq 0$ . Therefore, for  $k = 0$  and  $k = 1$ , we consider the framework of *promise* problems, which generalize decision problems by allowing to “ignore” inputs that do not satisfy the promised property (here, having at most  $k$  pairs of exchangeable literals). Note that all results hold in the classical decision framework if we apply weaker criteria that bound the number of potentially exchangeable literals and can be checked in polynomial time.

Finally, these results are extended in two ways. First, we point out that a  $\text{FOL}(\exists, \wedge, \neg_a)$  formula can be partitioned into subsets of literals called *pieces* (this notion is actually defined on PGs as it corresponds to a graph decomposition notion), such that the bound on the number of pairs of exchangeable literals can be made relative to each piece of  $g$  instead of the entire  $g$ , i.e., in all results, condition “ $g$  has at most  $k$  pairs of exchangeable literals” can be relaxed into “each piece of  $g$  has at most  $k$  pairs of exchangeable literals”. Second, we refine several notions related to exchangeable literals, in order to decrease their number.

**Paper organization.** Section 2 introduces the graph framework and known results. Section 3 studies properties of exchangeable literals. Section 4 contains our main complexity results. Section 5 is devoted to refinements. Section 6 synthe-

sizes related work and concludes this study.

## 2 Preliminaries

Since we do not consider function symbols other than constants, a *logical language* is a pair  $(\mathcal{R}, \mathcal{I})$ , where  $\mathcal{R}$  is the set of predicates and  $\mathcal{I}$  is the set of constants. The *terms* on  $(\mathcal{R}, \mathcal{I})$  are thus constants in  $\mathcal{I}$  or variables. Equality is not considered but all results are easily extended to it (see in particular [LM06], which shows how to include equality and inequality in the framework of polarized conceptual graphs). An *atom* on  $(\mathcal{R}, \mathcal{I})$  is of form  $p(t_1, \dots, t_n)$ ,  $n \geq 1$ , where  $p \in \mathcal{R}$  and, for all  $j$  in  $1, \dots, n$ ,  $t_j$  is a term on  $(\mathcal{R}, \mathcal{I})$ . Note that nullary predicates are not considered because their processing is trivial; the tools developed here would therefore be unnecessarily complicated for dealing with them. A *literal* on  $(\mathcal{R}, \mathcal{I})$  is an atom (positive literal) or the negation of an atom (negative literal) on  $(\mathcal{R}, \mathcal{I})$ . A FOL $(\exists, \wedge, \neg_a)$  formula on  $(\mathcal{R}, \mathcal{I})$  is an existentially closed conjunction of literals on  $(\mathcal{R}, \mathcal{I})$ . Without loss of generality, we consider that it is of the form  $\exists x_1 \dots x_q (l_1 \wedge \dots \wedge l_p)$ , where, for all  $i$  in  $1 \dots p$ ,  $l_i$  is a literal whose variables are in  $\{x_1, \dots, x_q\}$ . A FOL $(\exists, \wedge)$  formula has only positive literals. The set of *atoms occurring in a formula* is the set of atoms occurring positively or negatively in its literals.

As explained in the introduction, it is convenient to see a FOL $(\exists, \wedge, \neg_a)$  formula as a bipartite labeled graph, that we call a polarized graph (PG). The following definitions and results about polarized graphs are mainly based on [LM07] and [ML07].

**Definition 1 (polarized graph)** *Let  $\mathcal{V} = (\mathcal{R}, \mathcal{I})$  be a vocabulary where  $\mathcal{R}$  is a finite set of relation names of any arity and  $\mathcal{I}$  a set of individual names, or constants. A polarized graph (PG) is a finite undirected bipartite labeled multigraph  $G = (R, T, E, \lambda)$  where  $R$  and  $T$  are the (disjoint) sets of nodes, respectively called set of relation nodes and set of term nodes,  $E$  is the family of edges (there may be several edges with the same extremities, thus strictly speaking, a PG is a multigraph and not a graph) and  $\lambda$  is a labeling mapping of nodes and edges. For  $x \in R$ ,  $\lambda(x) = +r$  ( $x$  is called a positive relation node) or  $\lambda(x) = -r$  ( $x$  is called a negative relation node) where  $r \in \mathcal{R}$ ; the degree of  $x$  (i.e., the number of edges incident to it) must be equal to the arity of  $r$ ; furthermore, the edges incident to  $x$  are totally ordered, which is represented by labeling edges from 1 to the degree of  $x$ . An edge labeled  $i$  between a relation node  $x$  and a term node  $t$  is denoted  $(x, i, t)$ . For  $t \in T$ , either  $\lambda(t) = *$  ( $t$  is called a variable node) or  $\lambda(t) \in \mathcal{I}$  ( $t$  is called a constant node).*

Each PG can be put into a *normal* form, such that each constant of  $\mathcal{I}$  appears at

most once in it. In the following, a PG is assumed to be in this normal form unless otherwise specified.

A FOL( $\exists, \wedge, \neg_a$ ) formula  $g$  on a logical language  $(\mathcal{R}, \mathcal{I})$ , is translated into a PG  $G$  on a vocabulary  $\mathcal{V} = (\mathcal{R}, \mathcal{I})$ , with the following natural bijections: from variables in  $g$  to variable nodes in  $G$ , from constants in  $g$  to constant nodes in  $G$  (s.t. a constant  $a$  yields a node with label  $a$ ), from positive (resp. negative) literals in  $g$  to positive (resp. negative) relation nodes in  $G$  (s.t. the predicate and polarity of a literal yield the label of the relation node). For each argument  $t_i$  of a literal  $l$ , there is an edge  $(x, i, t)$ , where  $x$  is the relation node assigned to  $l$  and  $t$  is the term node assigned to  $t_i$ . There is thus a bijection from the set of FOL( $\exists, \wedge, \neg_a$ ) formulas on a logical language  $(\mathcal{R}, \mathcal{I})$  to the set of normal PGs without isolated term nodes<sup>4</sup> on a vocabulary  $\mathcal{V} = (\mathcal{R}, \mathcal{I})$ . This bijection is up to isomorphism for graphs and up to variable renaming for formulas. In the following, since we work on the graph representation of formulas, we will consider PGs as the basic constructs, and see formulas as their logical meaning. The mapping from PGs without isolated term nodes to formulas is called  $\Phi$ . Moreover, we will assume that PGs do not have redundant relation nodes (i.e., with the same label and the same  $i$ th neighbors), thus the associated formulas can be seen as sets of atoms.

**Notations.** Let  $+r(t_1, \dots, t_q)$  (resp.  $-r(t_1, \dots, t_q)$ ) denote the subgraph induced by a positive (resp. negative) relation node with label  $+r$  (resp.  $-r$ ) and its list of neighbors  $t_1, \dots, t_q$ . By analogy with its logical translation  $r(t_1, \dots, t_q)$  (resp.  $\neg r(t_1, \dots, t_q)$ ), in which  $t_i$  denotes the term assigned to the term node  $t_i$ , we also call it a *literal*. Let  $\sim r$  denote a label with relation name  $r$ , where  $\sim$  can be  $+$  or  $-$ . Given a literal (resp. a relation label)  $l$ ,  $\bar{l}$  denotes the *complementary* literal (resp. relation label) of  $l$ , i.e., it is obtained from  $l$  by reversing its sign. Letters  $u, v$  and  $w$  are used to denote a tuple  $(t_1, \dots, t_q)$  of terms (or term nodes). Thus  $\sim r(u)$  denotes a literal of arbitrary sign and arity. If  $\pi$  is a mapping from a set of terms (or term nodes) to a set of terms (or term nodes), then for  $u = (t_1, \dots, t_q)$ ,  $\pi(u)$  denotes the tuple  $(\pi(t_1), \dots, \pi(t_q))$ . A *substitution* of variables maps every variable to a term (variable or constant) and every constant to itself. Removing a literal from a graph means removing its relation node and the edges incident to it, so some term nodes of the removed literal may become isolated. If  $L$  is a set of literals of  $G$  then  $G \setminus L$  is the subgraph of  $G$  obtained from  $G$  by removing the literals in  $L$ . In a similar way, if  $G'$  is a subgraph of  $G$  then  $G \setminus G'$  is the subgraph of  $G$  obtained from  $G$  by removing the literals in  $G'$ .

**Definition 2 (inconsistent PG/set of literals)** A PG (or set of literals) is said to be inconsistent if it contains two complementary literals  $+r(u)$  and  $-r(u)$ . Otherwise

<sup>4</sup>A PG may have isolated term nodes, which cannot be obtained by the previous translation of a formula, but may arise for a subgraph of a PG.

it is said to be consistent.

It can be immediately checked that inconsistent PGs correspond to unsatisfiable formulas.

**Definition 3 (PG homomorphism)** A PG homomorphism from  $G = (R_G, T_G, E_G, l_G)$  to  $H = (R_H, T_H, E_H, l_H)$ , over the same vocabulary  $\mathcal{V} = (\mathcal{R}, \mathcal{I})$ , is a mapping  $\pi$  from  $R_G \cup T_G$  to  $R_H \cup T_H$ , such that:

1. for all  $r \in R_G$ ,  $\pi(r) \in R_H$  ; for all  $t \in T_G$ ,  $\pi(t) \in T_H$   
( $\pi$  preserves bipartition)
2. for all edge  $(r, i, t)$  in  $G$ ,  $(\pi(r), i, \pi(t))$  is in  $H$   
( $\pi$  preserves edges and their ordering)
3. for all  $r \in R_G$ ,  $l_H(\pi(r)) = l_G(r)$   
( $\pi$  preserves relation labels)
4. for all  $t \in T_G$ , if  $l_G(t) \in \mathcal{I}$  then  $l_H(\pi(t)) = l_G(t)$ , otherwise there is no condition on  $l_H(\pi(t))$   
( $\pi$  may “instantiate” variables).

If there is a homomorphism  $\pi$  from  $G$  to  $H$ , we say that  $G$  (or a subgraph of  $G$ ) is mapped to  $H$  by  $\pi$ . We call  $G$  the *source* graph and  $H$  the *target* graph. Given a literal  $l$  composed of a relation node  $r \in R_G$ , with label  $\sim p$ , and list of neighbors  $u$ ,  $\pi(l)$  denotes the literal composed of the relation node  $\pi(r)$  with list of neighbors  $\pi(u)$ , i.e., since  $\pi$  preserves relation labels,  $\pi(l)$  is the literal  $\sim p(\pi(u))$  in  $H$ .

**Proposition 1 (Substitution / PG Homomorphism Equivalence)** Let  $G$  and  $H$  be two PGs without isolated term nodes (with  $H$  being normal). There is a homomorphism from  $G$  to  $H$  if and only if there is a substitution  $\sigma$  of variables in  $\Phi(G)$  into terms in  $\Phi(H)$  such that for each literal  $\sim p(u)$  in  $\Phi(G)$ ,  $\sim p(\sigma(u))$  is a literal in  $\Phi(H)$ .

Positive PGs are translated into positive formulas; for this positive fragment it has been proven that PG homomorphism is sound and complete w.r.t. logical entailment, provided that the target graph is normal (basically [CM92], considering that positive PGs are a particular case of simple conceptual graphs). For general PGs, homomorphism is still sound:

**Proposition 2** Given two PGs  $G$  and  $H$ , if there is a homomorphism from  $G$  to  $H$  then  $\Phi(G)$  is entailed by  $\Phi(H)$ .

Figure 2: Non-completeness of PG homomorphism

Figure 3: When the law of the excluded-middle intervenes

However, it is no longer complete, as illustrated by Figure 2. In this figure, the formulas assigned to  $G$  and  $H$  by  $\Phi$  are respectively  $\Phi(G) = \exists x \exists y (p(x) \wedge \neg p(y) \wedge r(x, y))$  and  $\Phi(H) = p(a) \wedge r(a, b) \wedge r(b, c) \wedge \neg p(c)$ . One can check that  $\Phi(G)$  is entailed by  $\Phi(H)$ , using the tautology  $p(b) \vee \neg p(b)$  (indeed, every model of  $\Phi(H)$  satisfies either  $p(b)$  or  $\neg p(b)$ ; if it satisfies  $p(b)$ , then  $x$  and  $y$  are interpreted as  $b$  and  $c$ ; in the opposite case,  $x$  and  $y$  are interpreted as  $a$  and  $b$ ; thus every model of  $\Phi(H)$  is a model of  $\Phi(G)$ ).

As explained in the introduction, the law of the excluded-middle leads to consider all ways of *completing* the knowledge asserted by a PG. Let us look again at the example in Figure 2.  $H$  does not say whether  $p$  holds for  $b$ . We thus have to consider two cases: either a relation node with label  $+p$  or a relation node with label  $-p$  can be attached to  $b$ . Let  $H_1$  and  $H_2$  be the graphs respectively obtained from  $H$  (see Figure 3). There is a homomorphism from  $G$  to  $H_1$  and there is a homomorphism from  $G$  to  $H_2$ . We conclude that  $G$  is entailed by  $H$ .

**Definition 4 (Completion)** A consistent PG defined on a vocabulary  $\mathcal{V} = (\mathcal{R}_{\mathcal{V}}, \mathcal{I}_{\mathcal{V}})$  is complete w.r.t. a set of relation names  $\mathcal{R} \subseteq \mathcal{R}_{\mathcal{V}}$ , if for each  $r \in \mathcal{R}$  with arity

$q$ , for each  $q$ -tuple of not necessarily distinct term nodes  $(t_1, \dots, t_q)$ , it contains  $+r(t_1, \dots, t_q)$  or  $-r(t_1, \dots, t_q)$ . If such a PG  $H^c$  is obtained by adding relation nodes to a PG  $H$ , it is called a completion of  $H$  (w.r.t.  $\mathcal{R}$ ).

If a relation node  $\sim r(u)$  with  $r \in \mathcal{R}$  is added to a complete PG, either this relation node is redundant or it makes the PG inconsistent. A complete PG is obtained from a consistent PG  $G$  by repeatedly adding positive and negative relation nodes as long as a relation node bringing new information and not yielding an inconsistency can be added. Since a PG is a finite graph defined over a finite set of relation names, the number of different complete PGs that can be obtained from it is finite. We can now define the entailment problem on PGs in terms of completion.

**Definition 5 (PG-ENTAILMENT)** PG-ENTAILMENT takes two PGs  $G$  and  $H$  defined on a vocabulary  $\mathcal{V} = (\mathcal{R}_{\mathcal{V}}, \mathcal{I}_{\mathcal{V}})$  as input, with  $H$  being consistent, and asks whether  $G$  is PG-entailed by  $H$ , i.e., whether  $G$  can be mapped via homomorphism to each completion of  $H$  w.r.t.  $\mathcal{R}_{\mathcal{V}}$ .

The following theorem expresses that PG-ENTAILMENT is sound and complete with respect to FOL entailment.

**Theorem 1 [ML07]** Let  $G$  and  $H$  be two PGs without isolated term nodes, with  $H$  being consistent. Then  $G$  can be PG-entailed from  $H$  if and only if  $\Phi(H) \models \Phi(G)$ .

In the rest of the paper, we will thus not distinguish between logical entailment in the FOL( $\exists, \wedge, \neg_a$ ) fragment and PG-entailment, and use the expression “ $G$  is entailed by  $H$ ”.

Let us outline a brute-force algorithm scheme for PG-ENTAILMENT: all completions of  $H$  w.r.t. relation names occurring in  $G$  are generated from  $H$ , and for each of them it is checked whether  $G$  can be mapped to it. A complete graph to which  $G$  cannot be mapped can be seen as a counter-example to the assertion that  $G$  is entailed by  $H$ . Actually, not all relation names occurring in  $G$  need to be considered for completing  $H$ :

**Proposition 3 [LM07]** The relation names that do not have both positive and negative occurrences in  $G$  and in  $H$ , are not needed in the completions of  $H$  (i.e.,  $G$  is entailed by  $H$  if and only if  $G$  can be mapped to each completion of  $H$  w.r.t. the set of relation names that have both positive and negative occurrences in  $G$  and in  $H$ ).

From now on, completions of  $H$  are implicitly defined w.r.t. the set of relation names that have both positive and negative occurrences in  $G$  and in  $H$ , unless otherwise specified. This set of relation names will be referred to as the *completion vocabulary* w.r.t.  $(G, H)$ .

Figure 4: Exchangeable versus unifiable literals

### 3 Exchangeable Literals and Related Properties

This section defines exchangeable literals and related notions, and provides the basic theorems underlying the complexity results in Section 4.

Two literals are said to be *p-opposite* if they have the same predicate and opposite polarities (regardless of their arguments). Two *p-opposite* literals of  $G$  are said to be “exchangeable” if their arguments can have the same images by homomorphisms from  $G$  to (necessarily distinct) completions of  $H$ . More precisely:

**Definition 6 (Exchangeable pair/literal w.r.t.  $(G, H)$ )** A pair  $\{+p(u), -p(v)\}$  of *p-opposite* literals in  $G$  is exchangeable w.r.t.  $(G, H)$  if there are two completions of  $H$ , say  $H_1$  and  $H_2$ , and two homomorphisms  $\pi_1$  and  $\pi_2$ , respectively from  $G$  to  $H_1$  and from  $G$  to  $H_2$ , such that  $\pi_1(u) = \pi_2(v)$ . A literal in  $G$  is exchangeable w.r.t.  $(G, H)$  if it belongs to an exchangeable pair w.r.t.  $(G, H)$ .

In the following, exchangeable pairs and exchangeable literals are implicitly defined “w.r.t.  $(G, H)$ ” if not otherwise specified<sup>5</sup>.

See for instance  $G$  in Figure 2. The pair  $\{+p(x), -p(y)\}$  of *p-opposite* literals in  $G$  is exchangeable, as can be seen in Figure 3: there is a homomorphism  $\pi_1$  from  $G$  to a completion  $H_1$  of  $H$  and there is a homomorphism  $\pi_2$  from  $G$  to another completion  $H_2$  of  $H$ , such that  $\pi_1(x) = \pi_2(y)$  (and is the node in  $H$  with label  $b$ ).

If a pair of literals  $\{l_1, l_2\}$  is exchangeable then  $l_1$  and  $\bar{l}_2$  can be unified (after a renaming of their common variables), but the reverse is not generally true because

<sup>5</sup>Note that “w.r.t.  $H$ ” would not be sufficient. Indeed, a subgraph  $G'$  of  $G$  may contain literals that are exchangeable w.r.t.  $(G', H)$  but not w.r.t.  $(G, H)$ . In particular, the property “being without exchangeable pair of literals” is not inherited by the subgraphs.

the notion of exchangeable pair takes both the structure of  $G$  and the one of  $H$  into account. See for instance Figure 4, where  $l_1$  and  $\bar{l}_2$  are unifiable, as well as  $l_1$  and  $\bar{l}_3$ .  $\{l_1, l_2\}$  is an exchangeable pair, which can be seen with the following two completions of  $H$  (note that the completion vocabulary is restricted to  $p$ ): in one completion, say  $H_1$ ,  $-p(b)$  is added (and a homomorphism from  $G$  to  $H_1$  maps  $l_2$  to  $-p(b)$ ); in another completion, say  $H_2$ ,  $+p(b)$  and  $-p(d)$  are added (and a homomorphism from  $G$  to  $H_2$  maps  $l_1$  to  $+p(b)$ ). It can be checked that  $\{l_1, l_3\}$  is not an exchangeable pair: there are no two completions such that  $x$  and  $z$  can be mapped to the same node <sup>6</sup>.

We will now consider the subgraphs of  $G$  that do not contain any exchangeable pair w.r.t.  $(G, H)$ . A subgraph of  $G$  *without exchangeable pair w.r.t.  $(G, H)$*  is a subgraph of  $G$  containing at most one literal of each exchangeable pair w.r.t.  $(G, H)$ . A particular case is the *socle* of  $G$  (w.r.t.  $H$ ) which contains no exchangeable literal w.r.t.  $(G, H)$  at all.

**Definition 7 (Socle  $G_s$ )** *Given two PGs  $G$  and  $H$ , the socle of  $G$  w.r.t.  $H$ , denoted  $G_s^H$  (and simply  $G_s$  if not ambiguous), is the subgraph of  $G$  obtained from  $G$  by removing all exchangeable literals.*

We recall that removing a literal means removing its relation node and its incident edges. Thus the socle of  $G$  contains all term nodes in  $G$ . See Figure 2:  $G$  has one exchangeable pair  $\{+p(x), -p(y)\}$ . The subgraphs of  $G$  without exchangeable pair are the subgraphs of  $G$  not containing  $+p(x)$  or not containing  $-p(y)$ .  $G_s$  is the subgraph of  $G$  obtained by removing both relation nodes.

The following theorem is a key technical result, which underlies the main forthcoming results:

**Theorem 2** *Let  $G$  and  $H$  be two PGs, with  $H$  being consistent. If  $G$  is entailed by  $H$ , then, for each completion  $H^c$  of  $H$ , there is a homomorphism from  $G$  to  $H^c$  that maps  $G_s$  to  $H$ .*

*Proof:* Assuming that  $G$  is entailed by  $H$ , let  $H^c$  be a completion of  $H$ . Let  $R$  be the set of literals  $l$  in  $H^c \setminus H$  such that there is a homomorphism from  $G$  to  $H^c$  mapping some literal of  $G_s$  to  $l$ .  $R$  is consistent since it is a set of literals in  $H^c$ . Let  $H^{c'}$  be the completion of  $H$  obtained from  $H^c$  by replacing every literal of  $R$  by its complementary literal, and let  $\pi$  be a homomorphism from  $G$  to  $H^{c'}$  (such a homomorphism exists since  $G$  is entailed by  $H$ ). Let us show that  $\pi$  is a

---

<sup>6</sup>The restriction to relation names of the completion vocabulary (see Prop. 3) in completions of  $H$  is important; in the previous example,  $\{l_1, l_3\}$  would be an exchangeable pair if the relation name  $r$  was considered in completions of  $H$ .

homomorphism from  $G$  to  $H^c$  that maps  $G_s$  to  $H$ . No literal of  $G$  can be mapped by  $\pi$  to the complementary literal of a literal of  $R$  (otherwise this literal would be exchangeable with a literal of  $G_s$ , which contradicts the definition of  $G_s$ ). Thus  $\pi$  is a homomorphism from  $G$  to  $H^c$ . Therefore, by definition of  $R$ , every literal of  $G_s$  is mapped by  $\pi$  to either  $H$  or  $R$ . However, as  $\pi$  is a homomorphism from  $G$  to  $H^c$ , which contains no literal of  $R$ , no literal of  $G_s$  can be mapped to  $R$ , thus  $\pi$  maps  $G_s$  to  $H$ .  $\square$

Let  $H^{c+}$  (resp.  $H^{c-}$ ) be the positive (resp. negative) completion of  $H$  obtained by adding only positive (resp. negative) literals. As a corollary of the previous theorem, we obtain:

**Proposition 4** *Let  $G$  and  $H$  be two PGs, with  $H$  being consistent. Let  $G^-$  (resp.  $G^+$ ) be the subgraph of  $G$  defined by adding to  $G_s$  all negative (resp. positive) exchangeable literals in  $G$ . If  $G$  is entailed by  $H$ , then there is a homomorphism from  $G$  to  $H^{c+}$ , the positive completion of  $H$  (resp. to  $H^{c-}$ , the negative completion of  $H$ ), that maps  $G^-$  (resp.  $G^+$ ) to  $H$ .*

*Proof:* Let us prove the proposition for  $G^-$  and  $H^{c+}$  (the proof for  $G^+$  and  $H^{c-}$  is symmetric). If  $G$  is entailed by  $H$ , Th. 2 ensures that there is a homomorphism, say  $\pi$ , from  $G$  to  $H^{c+}$  that maps  $G_s$  to  $H$ . Since  $H^{c+}$  is obtained from  $H$  by adding positive literals,  $\pi$  maps all negative literals of  $G$  to  $H$ . Thus  $\pi$  maps  $G^-$  to  $H$ .  $\square$

If we consider any subgraph of  $G$  without exchangeable pair (w.r.t.  $(G, H)$ ), we have a weaker relationship between this subgraph and completions of  $H$ :

**Theorem 3** *Let  $G$  and  $H$  be two PGs, with  $H$  being consistent. Let  $G'$  be a subgraph of  $G$  without exchangeable pair w.r.t.  $(G, H)$ . If  $G$  is entailed by  $H$ , then there is a completion  $H^c$  of  $H$  and a homomorphism from  $G$  to  $H^c$  that maps  $G'$  to  $H$ .*

*Proof:* We suppose that  $G$  is entailed by  $H$ . Let  $R$  be the set of literals  $l$  such that there is a completion  $H^c$  of  $H$  such that  $l$  is a literal in  $H^c \setminus H$  and there is a homomorphism from  $G$  to  $H^c$  mapping some literal of  $G'$  to  $l$ .  $R$  is consistent since  $G'$  contains no exchangeable pair w.r.t.  $(G, H)$ . Let  $H^c$  be a completion of  $H$  containing the complementary literals of all literals of  $R$  (such a completion exists since  $R$  is consistent), and let  $\pi$  be a homomorphism from  $G$  to  $H^c$  (such a homomorphism exists since  $G$  is entailed by  $H$ ). Let us show that  $\pi$  maps  $G'$  to  $H$ . By definition of  $R$ , every literal of  $G'$  is mapped by  $\pi$  to either  $H$  or  $R$ . However, as  $\pi$  is a homomorphism from  $G$  to  $H^c$ , which contains no literal of  $R$ , no literal of  $G'$  can be mapped to  $R$ , so  $\pi$  maps  $G'$  to  $H$ .  $\square$

Th. 3 can be rephrased as follows: if  $G$  is entailed by  $H$ , then each subgraph  $G'$  of  $G$  without exchangeable pair can be mapped to  $H$  by a homomorphism that can be extended to a homomorphism from  $G$  to a completion of  $H$ . We will now define this notion of “extensible homomorphism” from a subgraph of  $G$  to  $H$  (Def. 9). We first restrict the subgraphs of interest to “completion subgraphs”:

**Definition 8 (Completion subgraph of  $G$ )** A completion subgraph of  $G$  (w.r.t.  $H$ ) is a graph obtained from  $G$  by removing some literals whose relation names belong to the completion vocabulary (w.r.t.  $(G, H)$ ).

In the following, we will consider completion subgraphs of  $G$  without exchangeable pairs. Note that  $G_s$  is such a subgraph; it is not necessarily the smallest with this property as it may still contain literals with relation names from the completion vocabulary.

**Definition 9 (Extensible homomorphism)** A homomorphism  $\pi$  from a completion subgraph  $G'$  of  $G$  to  $H$  is extensible (w.r.t.  $(G, H)$ ) if it satisfies

1. for any literal  $\sim r(u)$  in  $G \setminus G'$ ,  $\neg \bar{r}(\pi(u))$  is not in  $H$ ;
2. for any  $p$ -opposite literals  $+r(u)$  and  $-r(v)$  in  $G \setminus G'$ ,  $\pi(u) \neq \pi(v)$ .

Note that, as  $G'$  is a completion subgraph of  $G$ ,  $G'$  contains all term nodes of  $G$ , so  $\pi(u)$  is defined for any literal  $\sim r(u)$  in  $G \setminus G'$ . Conditions 1 and 2 are obviously necessary for  $\pi$  to be extendable to a homomorphism from  $G$  to a completion of  $H$ . The next proposition shows that they are also sufficient.

**Proposition 5** A homomorphism  $\pi$  from a completion subgraph  $G'$  of  $G$  to  $H$  is extensible (w.r.t.  $(G, H)$ ) if and only if it can be extended to a homomorphism from  $G$  to a completion of  $H$ .

*Proof:* Let  $\pi$  be a homomorphism from  $G'$  to  $H$ .  $\Leftarrow$ : Obvious.  $\Rightarrow$ : We suppose that  $\pi$  satisfies conditions 1 and 2. Let  $H'$  be the graph obtained from  $H$  by adding the literal  $\sim r(\pi(u))$  for every literal  $\sim r(u)$  in  $G \setminus G'$  such that  $\sim r(\pi(u))$  is not already present in  $H$ . For each added literal  $l$ , the literal  $\bar{l}$  is not in  $H$  by condition 1, and is not another added literal by condition 2. Thus  $H'$  is consistent. Moreover, as  $G'$  is a completion subgraph of  $G$ , the relation name of each literal in  $G \setminus G'$  belongs to the completion vocabulary. It follows that  $H'$  can be completed into a completion  $H^c$  of  $H$  and that  $\pi$  can be extended to a homomorphism from  $G$  to  $H^c$ .  $\square$

We obtain the following corollary of Th. 3 and Prop. 5.

**Corollary 1** *Let  $G$  and  $H$  be two PGs, with  $H$  being consistent. Let  $G'$  be a completion subgraph of  $G$  possessing no exchangeable pair w.r.t.  $(G, H)$ . If  $G$  is entailed by  $H$ , then there is an extensible homomorphism from  $G'$  to  $H$ .*

The previous properties provide necessary entailment conditions, and therefore sufficient non-entailment conditions. For instance, by Corollary 1, if we find a completion subgraph of  $G$  without exchangeable pair w.r.t.  $(G, H)$  such that there is no extensible homomorphism from  $G'$  to  $H$  then we know that  $G$  is not entailed by  $H$ .

The problem of checking whether there is an extensible homomorphism from  $G'$  to  $H$  (given PGs  $G$  and  $H$  and a completion subgraph  $G'$  of  $G$ ) is NP-complete. It is in NP since an extensible homomorphism from  $G'$  to  $H$  provides a polynomial certificate, and it is complete for NP since in the case where  $G' = G$ , it is equivalent to the NP-complete problem of checking homomorphism<sup>7</sup> from  $G$  to  $H$ .

## 4 Main Complexity Results

We now focus on the role of exchangeable literals in the problem complexity. It follows immediately from previous properties that the problem complexity falls into NP if  $G$  has no exchangeable pair (see also Section 4.2). A natural question that arises then is whether a bounded number of exchangeable pairs affects the complexity. The answer is yes, as we will show it.

To study this question, let us define the following family of problems, where  $k$  is the maximal number of exchangeable pairs in  $G$ , and is fixed for each problem.

ENTAILMENT <sub>$k$</sub>

*Input:* two PGs  $G$  and  $H$ , with  $H$  being consistent and  $G$  possessing at most  $k$  exchangeable pairs w.r.t.  $(G, H)$ .

*Question:* Is  $G$  entailed by  $H$ ?

For any integers  $k$  and  $k'$  such that  $k < k'$ , ENTAILMENT <sub>$k'$</sub>  is at least as difficult as ENTAILMENT <sub>$k$</sub> , since any graph  $G$  possessing at most  $k$  exchangeable pairs also possesses at most  $k'$  exchangeable pairs. For the following results, we recall that we assume that the arity of predicates is bounded by a constant.

---

<sup>7</sup>The NP-hardness of this problem can be easily checked, for instance with a straightforward reduction from the Clique problem [GJ79]; indeed, a classical undirected graph (which can be turned into a special PG) contains a  $k$ -clique if and only if there is a homomorphism from the  $k$ -clique to it.

## 4.1 Complexity of the Recognition Problem

A desirable property is that recognizing exchangeable literals is not difficult compared to PG-ENTAILMENT complexity, which is indeed the case:

**Proposition 6** *Let EXCHANGEABLE be the problem that takes two PGs  $G$  and  $H$  as input and asks if  $G$  possesses some exchangeable pair w.r.t.  $(G, H)$ . EXCHANGEABLE is NP-complete.*

*Proof:* EXCHANGEABLE is in NP: a polynomial certificate is given by a pair  $\{+p(u), -p(v)\}$  of literals in  $G$ , and the proof that it is exchangeable, i.e., two completions  $H_1$  and  $H_2$  of  $H$  with homomorphisms  $\pi_1$  from  $G$  to  $H_1$  and  $\pi_2$  from  $G$  to  $H_2$  such that  $\pi_1(u) = \pi_2(v)$ . For NP-completeness, a reduction is built from positive PG-HOMOMORPHISM (given two positive PGs  $G_1$  and  $G_2$ , is there a homomorphism from  $G_1$  to  $G_2$ ?). Let  $G_1$  and  $G_2$  be two positive PGs. “Gadgets” are added to  $G_1$  and  $G_2$ , yielding  $G'_1$  and  $G'_2$  respectively, such that there is a homomorphism from  $G_1$  to  $G_2$  if and only if  $G'_1$  possesses an exchangeable pair w.r.t.  $(G'_1, G'_2)$ . Consider, for instance, the graphs  $G$  and  $H$  in Figure 2, and choose relation names  $r$  and  $p$ , as well as the constants  $a$ ,  $b$  and  $c$ , such that they do not occur in  $G_1$  and  $G_2$ .  $G'_1$  (resp.  $G'_2$ ) is obtained by making the disjoint sum<sup>8</sup> of  $G_1$  and  $G$  (resp. of  $G_2$  and  $H$ ). The only candidate exchangeable pair in  $G'_1$  is

$$\{+p(x), -p(y)\}. \quad \square$$

The polynomial certificate used in the previous proof can be extended in a straightforward way to a polynomial certificate for the problem of deciding whether a graph possesses “at least  $k$  exchangeable pairs” (where  $k$  is fixed). It follows that this problem is NP-complete too. Thus, the problem of deciding whether a graph possesses at most  $k$  exchangeable pairs, i.e., the recognition problem associated with ENTAILMENT $_k$ , is co-NP-complete.

**Proposition 7** *The problem that takes two PGs  $G$  and  $H$  as input and asks if  $G$  possesses at most  $k$  exchangeable pairs w.r.t.  $(G, H)$  is co-NP-complete for any  $k \geq 0$ .*

The complexity of the recognition problem associated with ENTAILMENT $_k$  may be seen as restricting practical use of the results in this paper. However, most of these results can be used in a weaker form by replacing exchangeable pairs by pairs of  $p$ -opposite (or  $p$ -opposite and unifiable) literals, which can be recognized in linear time. For instance, Th. 2 still holds if  $G_s$  is replaced by the subgraph of  $G$  obtained from  $G$  by removing all pairs of  $p$ -opposite and unifiable literals, since this graph is a subgraph of  $G_s$ .

<sup>8</sup>The disjoint sum of two graphs  $A$  and  $B$  is the graph obtained by making the union of two disjoint copies of  $A$  and of  $B$ .

## 4.2 ENTAILMENT<sub>0</sub> and ENTAILMENT<sub>1</sub>

In this section, we will consider ENTAILMENT<sub>0</sub> and ENTAILMENT<sub>1</sub> as *promise* problems. A promise problem is a generalization of a decision problem where the input is promised to fulfill a given property [ESY84, Gol05]. We have to consider that framework since deciding whether an input is a correct instance is a co-NP-hard problem. We show that ENTAILMENT<sub>0</sub> and ENTAILMENT<sub>1</sub> are NP-complete when considered as promise problems.

**Proposition 8** *Let  $G$  and  $H$  be two PGs, with  $G$  having no exchangeable pair w.r.t.  $(G, H)$ , and  $H$  being consistent.  $G$  is entailed by  $H$  if and only if there is a homomorphism from  $G$  to  $H$ .*

*Proof:* If there is a homomorphism from  $G$  to  $H$  then  $G$  is entailed by  $H$  by Prop. 2. The converse follows from Th. 2 since  $G_s = G$  (or from Th. 3 with  $G' = G$ ).  $\square$

**Proposition 9** *The promise problem ENTAILMENT<sub>0</sub> is NP-complete.*

It follows that ENTAILMENT<sub>1</sub> is NP-hard. We will now prove that ENTAILMENT<sub>1</sub> is in NP. Let us first explain the ideas of the proof on Figure 5.  $G$  possesses one exchangeable pair  $\{+p(x), -p(y)\}$ . There is no homomorphism from  $G$  to  $H$ . But  $G$  can be mapped to every completion of  $H$  that contains  $-p(b)$  (with  $x$  and  $y$  being respectively mapped to  $a$  and  $b$ ). If a completion does not contain  $-p(b)$ , then it contains  $+p(b)$ , thus it remains to check that  $G$  is entailed by  $H_1 = H + \{+p(b)\}$ . The same reasoning is applied on  $H_1$ : there is no homomorphism from  $G$  to  $H_1$ , but  $G$  can be mapped to every completion of  $H_1$  that contains  $-p(c)$  (with  $x$  and  $y$  being respectively mapped to  $b$  and  $c$ ); it remains to check that  $G$  is entailed by  $H_2 = H_1 + \{+p(c)\}$ , which is the case since there is a homomorphism from  $G$  to  $H_2$ .  $G$  can thus be seen as “sliding” on a growing  $H$ , from a place allowing to map  $G \setminus \{-p(y)\}$  to a place allowing to map  $G \setminus \{+p(x)\}$ . We are sure that this sliding process will either succeed or stop by lack of homomorphism after a finite number of steps since  $H$  cannot grow infinitely.

These ideas directly lead to Algorithm 1. Note that  $G \setminus \{\sim p(u)\}$  is a completion subgraph without exchangeable pair. Thus, if there is no extensible homomorphism from  $G \setminus \{\sim p(u)\}$  to  $H$ , then  $G$  is not entailed by  $H$ ; otherwise, let  $\pi$  be such a homomorphism: either  $\sim p(\pi(u))$  is in  $H$  and there is a homomorphism from  $G$  to  $H$ , or, noticing that  $G$  is entailed by  $H + \{\sim p(\pi(u))\}$ , it remains to check that  $G$  is entailed by  $H + \{\overline{p}(\pi(u))\}$ , hence the recursive call.

**Proposition 10** *The algorithm ENTAILMENT<sub>1</sub> is correct.*

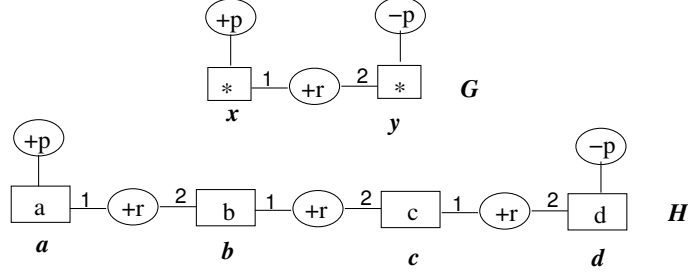

Figure 5: Illustration of Algorithm 1

---

**Algorithm 1:** ENTAILMENT<sub>1</sub>

---

**Data:**  $G$  and  $H$  two PGs;  $H$  is consistent;  $G$  possesses at most one exchangeable pair; if it has one,  $\sim p(u)$  is an exchangeable literal in  $G$  otherwise  $\sim p(u)$  is any literal in  $G$  such that relation name  $p$  belongs to the completion vocabulary w.r.t.  $(G, H)$ .

**Result:** true if  $G$  is entailed by  $H$ , false otherwise

**begin**

**if** there is no extensible homomorphism from  $G \setminus \{\sim p(u)\}$  to  $H$  **then**

**return** false

**else**

        let  $\pi$  be such a homomorphism

**if**  $\sim p(\pi(u))$  is in  $H$  **then**

**return** true

**else**

**return** ENTAILMENT<sub>1</sub>( $G, H + \{\sim p(\pi(u))\}, \sim p(u)$ )

*Proof:* We first check that the recursive call satisfies the precondition, i.e., that if there is at most one exchangeable pair w.r.t.  $(G, H)$  then there is at most one exchangeable pair w.r.t.  $(G, H + \{\sim p(\pi(u))\})$  and the precondition on  $\sim p(u)$  still holds. It is indeed the case, since any exchangeable pair w.r.t.  $(G, H + \{\sim p(\pi(u))\})$  is also an exchangeable pair w.r.t.  $(G, H)$ , as any completion of  $H + \{\sim p(\pi(u))\}$  is also a completion of  $H$  (note that the completions of  $H$  and of  $H + \{\sim p(\pi(u))\}$  are defined w.r.t. the same set of relation names since relation name  $p$  belongs to the completion vocabulary w.r.t.  $(G, H)$ ).

We also check that the number of recursive calls is finite, as the number of nodes of  $H$  is incremented at each recursive call (the added literal  $\sim p(\pi(u))$  is not already

present in  $H$  since  $\pi$  is extensible<sup>9</sup>), and is bounded by the number of literals in a completion of  $H$ .

Let us show by induction on the number  $k$  of recursive calls that  $\text{ENTAILMENT}_1(G, H, \sim p(u))$  returns true if  $G$  is entailed by  $H$ , and false otherwise. If  $k = 0$ , i.e., if there is no recursive call, then either there is no extensible homomorphism from  $G \setminus \{\sim p(u)\}$  to  $H$  (and then by Corollary 1  $G$  is not entailed by  $H$ ) and  $\text{ENTAILMENT}_1(G, H, \sim p(u))$  returns false, or  $\sim p(\pi(u))$  is in  $H$  (and then  $\pi$  can be extended to a homomorphism from  $G$  to  $H$ , so  $G$  is entailed by  $H$ ) and  $\text{ENTAILMENT}_1(G, H, \sim p(u))$  returns true. Thus the property is true for  $k = 0$ . We suppose that it is true for  $k$  recursive calls. Let us show that it is true for  $k + 1$  recursive calls. As there is at least one recursive call,  $\text{ENTAILMENT}_1(G, H, \sim p(u))$  returns true iff  $\text{ENTAILMENT}_1(G, H + \{\overline{\sim p}(\pi(u))\}, \sim p(u))$  returns true, i.e., by induction hypothesis, iff  $G$  is entailed by  $H + \{\overline{\sim p}(\pi(u))\}$ . It remains to show that  $G$  is entailed by  $H$  iff  $G$  is entailed by  $H + \{\overline{\sim p}(\pi(u))\}$ . If  $G$  is entailed by  $H$  then  $G$  is entailed by  $H + \{\overline{\sim p}(\pi(u))\}$  since every completion of  $H + \{\overline{\sim p}(\pi(u))\}$  is a completion of  $H$ . Conversely, we suppose that  $G$  is entailed by  $H + \{\overline{\sim p}(\pi(u))\}$ . As  $\pi$  is an extensible homomorphism from  $G \setminus \{\sim p(u)\}$  to  $H$ , it can be extended to a homomorphism from  $G$  to  $H + \{\sim p(\pi(u))\}$ . Thus  $G$  can be mapped to every completion of  $H + \{+p(\pi(u))\}$  and to every completion of  $H + \{-p(\pi(u))\}$ , and therefore to every completion of  $H$  (since any completion of  $H$  contains either  $H + \{+p(\pi(u))\}$  or  $H + \{-p(\pi(u))\}$ ). Hence  $G$  is entailed by  $H$ .  $\square$

The following proposition immediately follows from Algorithm 1.

**Proposition 11** *Let  $G$  and  $H$  be two PGs such that  $G$  has (at most) one exchangeable pair, containing literal  $\sim p(u)$  and  $H$  is consistent.  $G$  is entailed by  $H$  if and only if there is a sequence  $(\pi_i)_{i \in 1, \dots, m}$  such that:*

1.  $\pi_1$  is an extensible homomorphism from  $G \setminus \{\sim p(u)\}$  to  $H_1 = H$
2.  $\forall i \in 2, \dots, m - 1$ ,  
 $\pi_i$  is an extensible homomorphism from  $G \setminus \{\sim p(u)\}$  to  $H_i = H_{i-1} + \{\overline{\sim p}(\pi_{i-1}(u))\}$
3.  $\pi_m$  is a homomorphism from  $G$  to  $H_m = H_{m-1} + \{\overline{\sim p}(\pi_{m-1}(u))\}$ .

We are now able to prove the NP-completeness of  $\text{ENTAILMENT}_1$ .

**Theorem 4** *The promise problem  $\text{ENTAILMENT}_1$  is NP-complete.*

<sup>9</sup>Here, as  $G \setminus G'$  is restricted to literal  $\sim p(u)$ , conditions 1 and 2 of extensibility are restricted to:  $\overline{\sim p}(\pi(u))$  is not in  $H$ .

*Proof:* The polynomial certificate follows directly from Prop. 11. Indeed, the length  $m$  of the sequence is bounded by  $(n_H)^w$ , where  $n_H$  is the number of term nodes in  $H$  and  $w$  is the arity of  $r$  (which is considered as bounded by a constant).  $\square$

Note that Algorithm 1 still holds if  $G$  has an unbounded number of exchangeable pairs but only one positive (resp. negative) literal. It follows that the entailment problem remains NP-complete in that case. In contrast, the technique used in this algorithm does not seem to be generalizable to  $k \geq 2$ . Take for instance the case where  $k = 2$  and try to generalize Algorithm 1, replacing the literal  $\sim p(u)$  by two literals  $\sim p(u)$  and  $\sim q(v)$ . Then the recursive call with input  $H + \{\sim p(\pi(u))\}$  would be replaced by the conjunction of three recursive calls with inputs  $H + \{\sim p(\pi(u)), \sim q(\pi(v))\}$ ,  $H + \{\sim p(\pi(u)), \sim q(\pi(v))\}$  and  $H + \{\sim p(\pi(u)), \sim q(\pi(v))\}$  respectively, each of these recursive calls potentially generating three new recursive calls etc, so that generalized Prop. 11 would contain an exponential number of PGs  $H_i$  and homomorphisms  $\pi_i$ .

### 4.3 ENTAILMENT $_k$

We now show that, for any value of parameter  $k$ , ENTAILMENT $_k$  falls into the class  $P^{NP}$ , and even  $P_{\parallel}^{NP}$ , i.e., the class of decision problems solvable in polynomial time with one round of parallel queries to an NP oracle. Note that the condition on parallel queries can be relaxed by considering a constant number of rounds of parallel queries instead of a single round [BH91].

For that, we rely on Th. 2. We first deduce from this theorem a necessary and sufficient entailment condition (Prop. 12), which will be used in subsequent complexity proofs, and is also interesting for itself. Let us provide an idea of this condition on examples of Figures 2 and 5. For the graphs in Figure 2, if  $p(b)$  is known to be true (i.e., if literal  $+p(b)$  is added to  $H$ ) then  $G$  is entailed (i.e.,  $G$  can be mapped to  $H + \{+p(b)\}$ ), and if  $p(b)$  is known to be false then  $G$  is entailed too (i.e.,  $G$  can also be mapped to  $H + \{-p(b)\}$ ). Thus there are two extensible homomorphisms from  $G_s$  to  $H$ , which can be extended to homomorphisms from  $G$  to  $H + \{+p(b)\}$  and  $H + \{-p(b)\}$  respectively, with the formula  $p(b) \vee \neg p(b)$  being a tautology. We see  $p(b) \vee \neg p(b)$  as a propositional formula on a propositional language containing the atom  $p(b)$ ; if  $b$  was a variable node associated with variable  $z$ , the propositional language would contain the atom  $p(z)$  and the propositional tautology would be  $p(z) \vee \neg p(z)$ . Similarly, for the graphs in Figure 5, there are three extensible homomorphisms  $\pi_1$ ,  $\pi_2$  and  $\pi_3$  from  $G_s$  to  $H$ , which map  $G_s$  to  $+r(a, b)$ ,  $+r(b, c)$  and  $+r(c, d)$  respectively, and can be extended to homomorphisms from  $G$  to  $H + \{-p(b)\}$ ,  $H + \{+p(b), -p(c)\}$  and  $H + \{+p(c)\}$  respectively, with the proposition  $\neg p(b) \vee (p(b) \wedge \neg p(c)) \vee p(c)$  being a tautology.

We will build from the set of extensible homomorphisms from any completion subgraph  $G'$  of  $G$  contained in  $G_s$  to  $H$  a propositional formula that is a tautology if and only if  $G$  is entailed by  $H$ .

We define for each completion subgraph  $G'$  of  $G$  and each extensible homomorphism  $\pi$  from  $G'$  to  $H$  the set  $L(\pi)$  of literals that are “missing” in  $H$  for  $\pi$  to be extendable to a homomorphism from  $G$  to  $H$ . Therefore, the literals from  $L(\pi)$  have to be in any completion  $H^c$  of  $H$  such that  $\pi$  can be extended to a homomorphism from  $G$  to  $H^c$ . From  $L(\pi)$ , we define propositional formulas  $C(\pi)$  and  $D_{G'}(G, H)$  on a propositional language denoted  $P_H$ .

**Notations 1** *Let  $G$  and  $H$  be two PGs, with  $H$  being consistent, and let  $G'$  be a completion subgraph of  $G$ .*

*$P_H$  denotes the set of atoms occurring in  $\Phi(H^c \setminus H)$ , where  $H^c$  is an arbitrary completion of  $H$ .*

*For any extensible homomorphism  $\pi$  from  $G'$  to  $H$ ,  $L(\pi)$  denotes the set of literals  $l$  such that  $l = \sim p(\pi(u))$  for some literal  $\sim p(u)$  in  $G$  and  $l$  is not in  $H$ , and  $C(\pi)$  denotes the conjunction of the literals in  $L(\pi)$  which is a proposition on  $P_H$ .*

*$D_{G'}(G, H)$  denotes the disjunction of the propositions  $C(\pi)$  for all extensible homomorphisms  $\pi$  from  $G'$  to  $H$ .*

*Omission of subscript  $G'$  means that  $G'$  is equal to  $G_s$ .*

For instance, in the previous example of Figure 5, with  $P_H = \{p(b), p(c)\}$  and  $G' = G_s$ : let  $\pi_1, \pi_2$  and  $\pi_3$  be the extensible homomorphisms from  $G_s$  to  $H$ ;  $L(\pi_1) = \{-p(b)\}$ ,  $L(\pi_2) = \{+p(b), -p(c)\}$ ,  $L(\pi_3) = \{+p(c)\}$ ,  $C(\pi_1) = \neg p(b)$ ,  $C(\pi_2) = p(b) \wedge \neg p(c)$  and  $C(\pi_3) = p(c)$ ; finally,  $D(G, H) = \neg p(b) \vee (p(b) \wedge \neg p(c)) \vee p(c)$ .

Next Lemma 1 follows immediately from the definition of  $L(\pi)$ .

**Lemma 1** *Let  $G$  and  $H$  be two PGs, let  $H^c$  be a completion of  $H$ , let  $G'$  be a completion subgraph of  $G$ , and let  $\pi$  be an extensible homomorphism from  $G'$  to  $H$ . Then  $\pi$  can be extended to a homomorphism from  $G$  to  $H^c$  if and only if  $L(\pi)$  is a set of literals in  $H^c$ .*

Lemma 2 expresses the straightforward correspondence between the completions of  $H$  and the truth assignments on  $P_H$ .

**Lemma 2** *There is a bijection  $f$  from the set of completions of  $H$  to the set of truth assignments on  $P_H$  such that for any completion  $H^c$  of  $H$ , any completion subgraph  $G'$  of  $G$  and any extensible homomorphism  $\pi$  from  $G'$  to  $H$ ,  $L(\pi)$  is a set of literals in  $H^c$  if and only if  $f(H^c)$  satisfies  $C(\pi)$ .*

*Proof:* Let  $f$  be the mapping from the set of completions of  $H$  to the set of truth assignments on  $P_H$  defined as follows: for every completion  $H^c$  of  $H$ ,  $f(H^c)$  assigns the value true to an atom  $p(u)$  in  $P_H$  if  $+p(u)$  is a literal in  $H^c$ , and false otherwise (i.e., if  $-p(u)$  is a literal in  $H^c$ ).  $f$  clearly satisfies the desired conditions.  $\square$

**Proposition 12** *Let  $G$  and  $H$  be two PGs, with  $H$  being consistent, and let  $G'$  be any completion subgraph of  $G$  contained in  $G_s$ . Then  $G$  is entailed by  $H$  if and only if  $D_{G'}(G, H)$  is a tautology.*

*Proof:* By Th. 2 (since  $G'$  is contained in  $G_s$ ) and Prop. 5 (since  $G'$  is a completion subgraph of  $G$ ),  $G$  is entailed by  $H$  iff for each completion  $H^c$  of  $H$ , there is an extensible homomorphism from  $G'$  to  $H$  that can be extended to a homomorphism from  $G$  to  $H^c$ . Let us show that the latter proposition holds iff  $D_{G'}(G, H)$  is a tautology, using the bijection  $f$  of Lemma 2.  $\Rightarrow$ : We suppose that for each completion  $H^c$  of  $H$ , there is an extensible homomorphism from  $G'$  to  $H$  that can be extended to a homomorphism from  $G$  to  $H^c$ . Let us show that  $D_{G'}(G, H)$  is a tautology. Let  $v$  be a truth assignment on  $P_H$ , let us show that  $v$  satisfies  $D_{G'}(G, H)$ . Let  $H^c = f^{-1}(v)$ , and let  $\pi$  be an extensible homomorphism from  $G'$  to  $H$  that can be extended to a homomorphism from  $G$  to  $H^c$ . By Lemma 1,  $L(\pi)$  is a set of literals in  $H^c$ , so by Lemma 2,  $v$  satisfies  $C(\pi)$ , and therefore  $D_{G'}(G, H)$ .  $\Leftarrow$ : We suppose that  $D_{G'}(G, H)$  is a tautology. Let  $H^c$  be a completion of  $H$ , let us show that there is an extensible homomorphism from  $G'$  to  $H$  that can be extended to a homomorphism from  $G$  to  $H^c$ . Let  $v = f(H^c)$ . As  $D_{G'}(G, H)$  is a tautology, there is an extensible homomorphism  $\pi$  from  $G'$  to  $H$  such that  $v$  satisfies  $C(\pi)$ . By Lemmas 1 and 2,  $\pi$  can be extended to a homomorphism from  $G$  to  $H^c$ .  $\square$

In order to prove that  $\text{ENTAILMENT}_k$  is in  $P^{NP}$ , we show how to compute  $D(G, H)$  without explicitly computing all extensible homomorphisms from  $G_s$  to  $H$ , whose number may be exponential in the size of  $G$ . Let  $\mathcal{E}$  be the set of exchangeable literals, and  $\mathcal{T}_{\mathcal{E}}$  be the set of term nodes occurring in  $\mathcal{E}$ . The main idea is that, for any extensible homomorphism from  $G_s$  to  $H$ , the set  $L(\pi)$ , and therefore proposition  $C(\pi)$ , only depend on the restriction of  $\pi$  to  $\mathcal{T}_{\mathcal{E}}$ . Thus, we can define  $L(\varphi)$  and  $C(\varphi)$  for any mapping  $\varphi$  from  $\mathcal{T}_{\mathcal{E}}$  to the set  $T_H$  of term nodes in  $H$ , and  $D(G, H)$  is the disjunction of the propositions  $C(\varphi)$  for every mapping  $\varphi$  from  $\mathcal{T}_{\mathcal{E}}$  to  $T_H$  that can be extended to an extensible homomorphism from  $G_s$  to  $H$ . Note that a mapping  $\varphi$  from  $\mathcal{T}_{\mathcal{E}}$  to  $T_H$  can be extended to an extensible homomorphism from  $G_s$  to  $H$  iff it satisfies both following independent conditions: 1)  $\varphi$  can be extended to a homomorphism  $\pi$  from  $G_s$  to  $H$  and 2)  $\varphi$  satisfies conditions 1 and 2 of extensibility, which only depend on the restriction of  $\pi$  to  $\mathcal{T}_{\mathcal{E}}$ , i.e., on  $\varphi$  itself. According to Prop. 12, Algorithm 2 computes  $D(G, H)$  to determine whether  $G$  is entailed by  $H$ .

---

**Algorithm 2:** ENTAILMENT( $G, H$ )

---

**Data:**  $G$  and  $H$  two PGs, such that  $H$  is consistent  
**Result:** true if  $G$  is entailed by  $H$ , false otherwise  
**begin**  
    Let  $\mathcal{E}$  be the set of exchangeable literals w.r.t.  $(G, H)$   
    Let  $\mathcal{T}_{\mathcal{E}}$  be the set of term nodes occurring in  $\mathcal{E}$   
    Let  $G_s = G \setminus \mathcal{E}$   
     $\Phi \leftarrow false$   
    **for** every mapping  $\varphi$  from  $\mathcal{T}_{\mathcal{E}}$  to the set of term nodes in  $H$  **do**  
        **if**  $\varphi$  can be extended to an extensible homomorphism from  $G_s$  to  $H$   
            **then**  
                 $\Phi \leftarrow \Phi \vee C(\varphi)$   
    **return** Tautology( $\Phi$ )

---

If the number of exchangeable pairs is bounded by a constant  $k$ , then the number of mappings from  $\mathcal{T}_{\mathcal{E}}$  to the set of term nodes in  $H$  becomes polynomial, which makes ENTAILMENT $_k$  fall into  $P^{NP}$ .

**Theorem 5** For any integer  $k \geq 0$ , the decision problem ENTAILMENT $_k$  is in  $P_{||}^{NP}$ .

*Proof:* It is sufficient to give an algorithm that can be executed in polynomial time with a fixed number of rounds of parallel calls to an NP-oracle. We first check with a single round whether the input is a correct instance of ENTAILMENT $_k$ , which can be done by checking each pair of literals in  $G$ . If the input is correct, we call Algorithm 2. This algorithm performs three rounds of parallel calls:

- to compute  $\mathcal{E}$ , it is sufficient to determine for each pair of  $p$ -opposite literals in  $G$  (whose number is polynomial) if it is exchangeable, which is in NP (first round),
- $|\mathcal{T}_{\mathcal{E}}| \leq 2kw$ , where  $w$  is the maximal arity of a relation name, so the number of mappings from  $\mathcal{T}_{\mathcal{E}}$  to the set of term nodes in  $H$  is bounded by  $(n_H)^{2kw}$ , and therefore is polynomial,
- determining if such a mapping  $\varphi$  can be extended to an extensible homomorphism from  $G_s$  to  $H$  is in NP, since an extension provides a polynomial certificate (second round),
- determining if a proposition is not a tautology is in NP (third round).  $\square$

It follows from Algorithm 2 that in any case where it can be decided in polynomial time whether the formula  $\Phi$  computed by this algorithm is a tautology, the entailment problem is in NP. A polynomial certificate is given by a set of extensible homomorphisms  $\pi$  from  $G$  to  $H$  extending the mappings  $\varphi$  considered in this

algorithm (one for each extendable mapping  $\varphi$ , so that the number of homomorphisms  $\pi$  is polynomial), since computing the disjunction of the formulas  $C(\pi)$  and checking that it is a tautology can be done in polynomial time (we do not need to compute the set  $\mathcal{E}$  of exchangeable literals nor  $G_s$  nor the mappings  $\varphi$  themselves). In particular, it can be decided in polynomial time whether a disjunction of conjunctions of literals in which each conjunction contains at most one positive literal (or each conjunction contains at most one negative literal) is a tautology. It follows that  $\text{ENTAILMENT}_1$  is in NP, which provides a new proof of Th. 4 and of the fact that the entailment problem remains NP-complete if  $G$  has an unbounded number of exchangeable pairs but only one positive (resp. negative) literal.

#### 4.4 $\text{ENTAILMENT}_3$

We first prove that  $\text{ENTAILMENT}_3$  is co-NP-hard with a reduction from “3-DNF Tautology”. This reduction will be reused to prove the  $P_{||}^{NP}$ -hardness of  $\text{ENTAILMENT}_3$ .

**Theorem 6** *The problem  $\text{ENTAILMENT}_3$  is co-NP-hard.*

*Proof:* To prove that  $\text{ENTAILMENT}_3$  is co-NP-hard, we define a reduction from the co-NP-complete problem 3-DNF Tautology to  $\text{ENTAILMENT}_3$ .

##### **3-DNF Tautology**

*Input:* a 3-DNF propositional formula  $\Phi$ , i.e., a proposition  $\Phi$  in disjunctive normal form (disjunction of conjunctions of literals) such that each conjunction in  $\Phi$  has at most 3 literals.

*Question:* Is  $\Phi$  a tautology?

The reduction uses Prop. 12. Let  $\Phi$  be a 3-DNF proposition. By Prop. 12, it is sufficient to build two PGs  $G$  and  $H$  in polynomial time, with  $H$  being consistent and containing at most 3 exchangeable pairs, such that for some completion subgraph  $G'$  of  $G$  contained in  $G_s$ ,  $D_{G'}(G, H)$  is a tautology iff  $\Phi$  also is.

It is rather easy to build such PGs  $G$  and  $H$  with at most 9 exchangeable pairs. To ensure that they have at most 3 exchangeable pairs, we have to refine the construction. For this, we introduce the notion of *exchange-reducing* mapping w.r.t.  $\Phi$  (standing for “mapping allowing to reduce the number of exchangeable pairs in the graph  $G$  built by the reduction”). We will build a graph  $G$  with 3 positive literals and 3 negative literals with relation name  $p$ . Using an exchange-reducing mapping in the construction of graph  $H$  will make each positive literal  $+p(u)$  in  $G$  be potentially exchangeable with only one negative literal, which reduces the number of potential exchangeable pairs from 9 to 3. This will be explained in the last paragraph of this proof.

Let  $P$  be the set of atoms occurring in  $\Phi$ . A mapping  $\alpha$  from  $P$  to  $\{1, 2, 3\}$  is said to be *exchange-reducing* (w.r.t.  $\Phi$ ) if for any conjunction  $C$  in  $\Phi$  and any positive literals  $p$  and  $p'$  (resp. negative literals  $\neg p$  and  $\neg p'$ ) in  $C$ ,  $\alpha(p) \neq \alpha(p')$ .

For instance, if  $\Phi = (\neg p \wedge \neg s) \vee (s \wedge \neg q \wedge \neg r) \vee (p \wedge q \wedge r)$  then the mapping  $\alpha = \{(p, 1), (q, 2), (r, 3), (s, 2)\}$  is exchange-reducing. Note that there may be no exchange-reducing mapping w.r.t. a given  $\Phi$ . For instance, if  $\Phi = (p \wedge q \wedge r) \vee (p \wedge q \wedge s) \vee (r \wedge s)$  then an exchange-reducing mapping  $\alpha$  should satisfy  $\alpha(r) = \alpha(s)$  from the two first conjunctions, and  $\alpha(r) \neq \alpha(s)$  from the third conjunction.

In the first step of the proof, we will describe how to build in polynomial time from a 3-DNF proposition  $\Phi$  both a 3-DNF proposition  $\Phi'$ , such that  $\Phi'$  is a tautology iff  $\Phi$  is, and an exchange-reducing mapping  $\alpha$  w.r.t.  $\Phi'$  (which will necessarily exist). In the second step, we will describe how to build PGs  $G$  and  $H$  with at most 3 exchangeable pairs from a 3-DNF  $\Phi$  and an exchange-reducing mapping w.r.t.  $\Phi$ , such that for some completion subgraph  $G'$  of  $G$  contained in  $G_s$ ,  $D_{G'}(G, H)$  is a tautology iff  $\Phi$  is.

### 1. Construction of $\Phi'$ and $\alpha$

For each atom  $p$  in  $P$ , let  $h$  be the number of occurrences of  $p$  in  $\Phi$ . These  $h$  occurrences are replaced by  $h$  new atoms  $p_1, p_2, \dots, p_h$ , and the 3-DNF formula  $NEQ(p_1, \dots, p_h) = (p_1 \wedge \neg p_2) \vee (p_2 \wedge \neg p_3) \vee \dots \vee (p_{h-1} \wedge \neg p_h) \vee (p_h \wedge \neg p_1)$  is added to the disjunction.  $\Phi'$  is the obtained formula. For instance, if  $\Phi = (\neg p \wedge \neg s) \vee (s \wedge \neg q \wedge \neg r) \vee (p \wedge q \wedge r)$  then  $\Phi' = (\neg p_1 \wedge \neg s_1) \vee (s_2 \wedge \neg q_1 \wedge \neg r_1) \vee (p_2 \wedge q_2 \wedge r_2) \vee NEQ(p_1, p_2) \vee NEQ(q_1, q_2) \vee NEQ(r_1, r_2) \vee NEQ(s_1, s_2)$ . Note that a truth assignment satisfies  $NEQ(p_1, \dots, p_h)$  iff it does not assign the same truth value to all  $p_1, \dots, p_h$ . It follows that  $\Phi'$  is a tautology iff it is satisfied by each truth assignment assigning the same truth value to  $p_1, \dots, p_h$  for each atom  $p$  in  $P_H$ . Thus  $\Phi'$  is a tautology iff  $\Phi$  is.

An exchange-reducing mapping  $\alpha$  w.r.t.  $\Phi'$  is built as follows: for each conjunction in  $\Phi'$  coming from a conjunction in  $\Phi$  (considered independently of the others), atoms of positive (resp. negative) literals are mapped to consecutive integers starting from 1;  $\alpha$  is the union of the mappings obtained for these conjunctions. For instance, if  $\Phi' = (\neg p_1 \wedge \neg s_1) \vee (s_2 \wedge \neg q_1 \wedge \neg r_1) \vee (p_2 \wedge q_2 \wedge r_2) \vee NEQ(p_1, p_2) \vee NEQ(q_1, q_2) \vee NEQ(r_1, r_2) \vee NEQ(s_1, s_2)$  then we independently define  $\alpha_1 = \{(p_1, 1), (s_1, 2)\}$ ,  $\alpha_2 = \{(s_2, 1), (q_1, 1), (r_1, 2)\}$  and  $\alpha_3 = \{(p_2, 1), (q_2, 2), (r_2, 3)\}$ , and  $\alpha = \alpha_1 \cup \alpha_2 \cup \alpha_3$ . It is easy to check that  $\Phi'$  and  $\alpha$  can be computed in polynomial time and that  $\alpha$  is exchange-reducing w.r.t.  $\Phi'$ .

## 2. Construction of $G$ and $H$

Let  $\Phi$  be a 3-DNF formula and  $\alpha$  be an exchange-reducing mapping w.r.t.  $\Phi$ . PGs  $G$  and  $H$  are defined as follows (see Figure 6 for an illustration).

$G$  is independent of  $\Phi$  and  $\alpha$ . It has 6 variable nodes  $x_1, x_2, x_3, y_1, y_2$  and  $y_3$ , and 7 literals:  $+r(x_1, x_2, x_3, y_1, y_2, y_3)$  and, for all  $i$  in  $1, \dots, 3$ ,  $+p(x_i)$  and  $-p(y_i)$ .  $H$  depends from  $\Phi$  and  $\alpha$ . Let  $p_1, \dots, p_h$  be the atoms in  $\Phi$ , and let  $C_1, \dots, C_q$  be the conjunctions in  $\Phi$ .  $H$  has  $h + 2$  constant nodes labeled with  $a_1, \dots, a_h, c$  and  $d$ , and it has  $q + 2$  literals:  $+p(c)$ ,  $-p(d)$  and, for all  $i$  in  $1, \dots, q$ ,  $+r(u_i)$ , with  $u_i = (s_{i,1}, s_{i,2}, s_{i,3}, t_{i,1}, t_{i,2}, t_{i,3})$  being defined as follows. For all  $i$  in  $1, \dots, q$  and all  $j$  in  $1, \dots, 3$ :

- if  $j = \alpha(p_k)$  for some positive literal  $p_k$  in  $C_i$  (there is at most one such literal  $p_k$  since  $\alpha$  is exchange-reducing) then  $s_{i,j} = a_k$  else  $s_{i,j} = c$ ,
- if  $j = \alpha(p_k)$  for some negative literal  $\neg p_k$  in  $C_i$  (there is at most one such literal  $\neg p_k$  since  $\alpha$  is exchange-reducing) then  $t_{i,j} = a_k$  else  $t_{i,j} = d$ .

For instance, consider the formula of the previous example:  $(\neg p \wedge \neg s) \vee (s \wedge \neg q \wedge \neg r) \vee (p \wedge q \wedge r)$ . Let us rename  $p, q, r$  and  $s$  into  $p_1, p_2, p_3$  and  $p_4$  respectively. We obtain  $\Phi = (\neg p_1 \wedge \neg p_4) \vee (p_4 \wedge \neg p_2 \wedge \neg p_3) \vee (p_1 \wedge p_2 \wedge p_3)$ . Let  $\alpha = \{(p_1, 1), (p_2, 2), (p_3, 3), (p_4, 2)\}$ . Then the literals of  $H$  labeled with  $+r$  are  $+r(c, c, c, a_1, a_4, d)$ ,  $+r(c, a_4, c, d, a_2, a_3)$  and  $+r(a_1, a_2, a_3, d, d, d)$ , as pictured in Figure 6.

$G$  and  $H$  can be constructed in polynomial time. The completion vocabulary is restricted to  $\{p\}$ . Let  $G'$  be the subgraph of  $G$  restricted to its literal  $+r(x_1, x_2, x_3, y_1, y_2, y_3)$ .  $G'$  is a completion subgraph of  $G$  contained in  $G_s$ . Let us show that  $D_{G'}(G, H)$  is a tautology iff  $\Phi$  is. There are exactly  $q$  extensible homomorphisms  $\pi_1, \dots, \pi_q$  from  $G'$  to  $H$  such that for all  $i$  in  $1, \dots, q$ ,  $\pi_i$  maps  $G'$  to the literal  $+r(u_i)$  and  $C(\pi_i)$  is the formula obtained from  $C_i$  by replacing each atom  $p_j$  by  $p(a_j)$ . It follows that  $D_{G'}(G, H)$  is obtained from  $\Phi$  by replacing each atom  $p_j$  by  $p(a_j)$ . For instance, in the example of Figure 6, there are 3 extensible homomorphisms from  $G'$  to  $H$ , and  $D_{G'}(G, H) = (\neg p(a_1) \wedge \neg p(a_4)) \vee (p(a_4) \wedge \neg p(a_2) \wedge \neg p(a_3)) \vee (p(a_1) \wedge p(a_2) \wedge p(a_3))$ . Hence  $D_{G'}(G, H)$  is a tautology iff  $\Phi$  is.

It remains to show that there are at most 3 exchangeable pairs w.r.t.  $(G, H)$ . There are 9 pairs of  $p$ -opposite literals in  $G$ , namely the pairs  $\{+p(x_i), -p(y_j)\}$  for  $i, j$  in  $1, \dots, 3$ . However, if  $x_i$  and  $y_j$  are mapped to the same node  $z$  in  $H$  by two homomorphisms from  $G$  to completions of  $H$ , then there is an integer  $k$  in  $1, \dots, h$  such that  $z$  is labeled  $a_k$ , with  $i = j = \alpha(p_k)$ . Thus, each exchangeable pair must be of the form  $\{+p(x_i), -p(y_i)\}$ , with  $i$  in  $1, \dots, 3$ . As announced at the beginning of this proof, using an exchange-reducing mapping w.r.t.  $\Phi$  to define  $H$  allows to bound the number of exchangeable pairs to 3 instead of 9.  $\square$

**Theorem 7** *The problem  $\text{ENTAILMENT}_3$  is  $P_{||}^{NP}$ -complete.*

$$\Phi = (\neg p_1 \wedge \neg p_4) \vee (p_4 \wedge \neg p_2 \wedge \neg p_3) \vee (p_1 \wedge p_2 \wedge p_3)$$

$$\alpha = \{(p_1, 1), (p_2, 2), (p_3, 3), (p_4, 2)\}$$

Figure 6: Reduction from 3-DNF Tautology to ENTAILMENT<sub>3</sub>

Th. 5 shows  $P_{||}^{NP}$ -membership. We thus prove  $P_{||}^{NP}$ -hardness. We will rely on the following lemmas.

**Lemma 3** *For any problem  $A$  in  $NP$ , there is a translation  $f$  mapping every instance  $I$  of  $A$  to an instance  $f(I) = (f_G(I), f_H(I))$  of  $\text{ENTAILMENT}$  such that:*

- $f_G(I)$  is entailed by  $f_H(I)$  if and only if  $I$  is a positive instance of  $A$ ,
- $f_G(I)$  and  $f_H(I)$  do not contain any negative literal,
- $f_G(I)$  and  $f_H(I)$  do not contain any constant node.

*Proof:* As  $\text{ENTAILMENT}$  on PGs that do not contain any negative literal is NP-complete, there is a translation  $f$  satisfying the two first conditions on  $f(I)$ . In order to satisfy the third condition, we modify  $G = f_G(I)$  and  $H = f_H(I)$  as follows: for each constant  $a$  appearing in  $G$  or in  $H$ , replace the constant node labeled  $a$  in  $G$  (respectively  $H$ ) by a variable node  $x$  and add the literal  $+p_a(x)$  to  $G$  (respectively  $H$ ), where  $p_a$  is a new unary relation name, i.e., that does not occur in  $G$  nor in  $H$ .  $\square$

**Lemma 4** *There is a PG  $G$  and a set  $Q$  of 3 pairs of  $p$ -opposite literals in  $G$  such that for any problem  $B$  in  $co-NP$ , there is a translation  $g$  mapping every instance  $J$  of  $B$  to an instance  $g(J) = (g_G(J), g_H(J))$  of  $\text{ENTAILMENT}_3$  such that:*

- $g_G(J)$  is entailed by  $g_H(J)$  if and only if  $J$  is a positive instance of  $B$ ,
- $g_G(J) = G$ , each exchangeable pair w.r.t.  $(G, g_H(J))$  is in  $Q$ , and the set of relation node labels in  $g_H(J)$  is the same as in  $G$ ,
- $G$  and  $g_H(J)$  do not contain any constant node.

*Proof:* As 3-DNF Tautology is co-NP-complete, it is sufficient to prove the existence of the translation  $g$  in the case where  $B$  is 3-DNF Tautology. In that case it is sufficient to define the translation  $g$  as in the proof of Th. 6, except that the term nodes of  $H$  are defined as variable nodes instead of constant nodes, with  $Q = \{(+p(x_i), -p(y_i)), 1 \leq i \leq 3\}$ , the set of relation node labels being equal to  $\{+p, -p, +r\}$  in  $g_H(J)$  and in  $G$ .  $\square$

*Proof:* [of Theorem 7] We build a reduction from the following problem, known to be  $P_{||}^{NP}$ -complete [SV00]:

**Min-card-vertex cover compare**

*Input:* two undirected graphs  $F_1 = (V_1, E_1)$  and  $F_2 = (V_2, E_2)$ .

*Question:* Does  $\min\text{-vc}(F_1) \leq \min\text{-vc}(F_2)$ , where  $\min\text{-vc}(F_i)$  denotes the minimum cardinality of a vertex cover<sup>10</sup> of  $F_i$ ?

Let  $(F_1, F_2)$  be an instance of Min-card-vertex cover compare. We have to build two PGs  $G'$  and  $H'$  such that (1)  $G'$  has at most 3 exchangeable pairs w.r.t.  $(G', H')$  and (2)  $\min\text{-vc}(F_1) \leq \min\text{-vc}(F_2)$  if and only if  $G'$  is entailed by  $H'$ .

Let  $i$  be an integer. Since deciding whether the minimum size of a vertex cover of  $F_1$  is less than  $i$  is in NP, from Lemma 3, there is an instance of ENTAILMENT  $f(F_1, i) = (f_G(F_1, i), f_H(F_1, i))$  such that  $\min\text{-vc}(F_1) \leq i$  iff  $f_G(F_1, i)$  is entailed by  $f_H(F_1, i)$ , and  $f_G(F_1, i)$  and  $f_H(F_1, i)$  do not contain any negative literal or constant node. Similarly, since deciding whether the minimum size of a vertex cover of  $F_2$  is more than  $i$  is in co-NP, from Lemma 4, there is a PG  $G$ , a set  $Q$  of 3 pairs of  $p$ -opposite literals in  $G$  and an instance of ENTAILMENT<sub>3</sub>  $g(F_2, i) = (g_G(F_2, i), g_H(F_2, i))$  such that  $i \leq \min\text{-vc}(F_2)$  iff  $g_G(F_2, i)$  is entailed by  $g_H(F_2, i)$ ,  $g_G(F_2, i) = G$ , each exchangeable pair w.r.t.  $(G, g_H(F_2, i))$  is in  $Q$ , the set of relation node labels in  $g_H(F_2, i)$  is the same as in  $G$ , and  $G$  and  $g_H(F_2, i)$  do not contain any constant node, with  $G$  and  $Q$  being independent of  $i$ . Let  $G_i = f_G(F_1, i)$ ,  $H_i = f_H(F_1, i)$  and  $H'_i = g_H(F_2, i)$ . Comparing the sizes of the minimum vertex covers for  $F_1$  and  $F_2$  can be done by asking  $q + 1$  questions, where  $q = |V_2|$ : is there some  $i$ ,  $0 \leq i \leq q$ , such that  $\min\text{-vc}(F_1) \leq i$  and  $i \leq \min\text{-vc}(F_2)$ , i.e., such that  $G_i$  is entailed by  $H_i$  and  $G$  is entailed by  $H'_i$ ? Thus we have to build  $G'$  and  $H'$  from the PGs  $G_i$ ,  $H_i$ ,  $G$  and  $H'_i$  such that (1)  $G'$  has at most 3 exchangeable pairs w.r.t.  $(G', H')$  and (2)  $G'$  is entailed by  $H'$  if and only if there is some  $i$ ,  $0 \leq i \leq q$ , such that  $G_i$  is entailed by  $H_i$  and  $G$  is entailed by  $H'_i$ . This construction is illustrated by Figures 7 and 8. Let  $p_0, \dots, p_q$  be  $q + 1$  new binary relation names, i.e., that do not appear in any  $G_i$ ,  $H_i$ ,  $G$  and  $H'_i$ .  $G'$  is the PG obtained from the disjoint union of the  $G_j$  and of  $G$  by adding:

- $q + 1$  variables nodes  $v_0, \dots, v_q$  ( $v_i$  allows to link  $G$  to  $G_i$ ),
- $q + 1$  literals  $+p_0(v_0), \dots, +p_q(v_q)$ ,
- for each  $j$  in  $[0, q]$  and each term node  $x$  in  $G$ , the literal  $+out(x, v_j)$ ,
- for each  $j$  in  $[0, q]$  and each term node  $x$  in  $G_i$ , the literal  $+in(v_j, x)$ .

$H'$  is the disjoint union of the  $A_i$ ,  $0 \leq i \leq q$ , where  $A_i$  is built as  $G'$ , except that  $G$  is replaced by  $H'_i$ ,  $G_i$  is replaced by  $H_i$  and variable nodes  $v_j$  are renamed  $v_j^i$ . Note that since no  $G_i$ ,  $H_i$  and  $H'_i$  contains any constant node,  $H'$  is normal.

<sup>10</sup>A vertex cover of  $F$  is a set  $S$  of vertices such that each edge is adjacent to at least a vertex of  $S$ .

Figure 7: A sketch of  $G'$

Figure 8: A sketch of  $H'$

In the following, exchangeable pairs of  $G_i$  (respectively  $G, G'$ ) and completions of  $H_i$  (respectively  $H'_i, H'$ ) are implicitly defined w.r.t.  $(G_i, H_i)$  (respectively  $(G, H'_i), (G', H')$ ). For any subgraph  $K$  and any completion  $H'^c$  of  $H'$ , the part  $K$  of  $H'^c$  denotes the subgraph of  $H'^c$  obtained from  $K$  by adding the literals of  $H'^c \setminus H'$  whose terms are in  $K$ . We first prove the following lemma.

**Lemma 5** *For any completion  $H'^c$  of  $H'$  and any homomorphism  $\pi$  from  $G'$  to  $H'^c$ , there exist an integer  $i$  in  $[0, q]$ , a completion  $H_i^c$  of  $H_i$  and a completion  $H'_i{}^c$  of  $H'_i$  such that  $H_i^c$  is a subgraph of the part  $H_i$  of  $H'^c$ ,  $H'_i{}^c$  is a subgraph of the part  $H'_i$  of  $H'^c$ , and  $\pi$  maps  $G_i$  to  $H_i^c$  and  $G$  to  $H'_i{}^c$ .*

*Proof:* Let  $H'^c$  be a completion of  $H'$  and let  $\pi$  be a homomorphism from  $G'$  to  $H'^c$ . As  $G'$  is connected, there is an integer  $i$  in  $[0, q]$  such that  $\pi$  maps  $G'$  to the part  $A_i$  of  $H'^c$ . Because of the relation name  $p_i$ , the literal  $+p_i(v_i)$  is mapped to  $+p_i(v_i^i)$ , so because of the relation nodes labeled  $+in$  and  $+out$  adjacent to  $v_i$  in  $G'$  and to  $v_i^i$  in  $H'^c$ ,  $\pi$  maps  $G$  to the part  $H'_i$  of  $H'^c$  and  $G_i$  to the part  $H_i$  of  $H'^c$ . As the sets of relation names appearing in the different pairs  $(G_j, H_j)$  and in  $G$  are pairwise disjoint and the set of relation node labels in  $H'_j$  is the same as in  $G$  for each  $j$ , the completion vocabulary w.r.t.  $(G', H')$  is the disjoint union of the completion vocabularies w.r.t. the different pairs  $(G_j, H_j)$  and of the pair  $(G, H'_i)$ . Let  $H_i^c$  be the subgraph of the part  $H_i$  of  $H'^c$  obtained by removing all relation nodes whose relation name does not appear in  $(G_i, H_i)$ .  $H_i^c$  is a completion of  $H_i$ , and  $\pi$  maps  $G_i$  to  $H_i^c$ . Similarly, let  $H'_i{}^c$  be the subgraph of the part  $H'_i$  of  $H'^c$  obtained by removing all relation nodes whose relation name does not appear in  $G$ .  $H'_i{}^c$  is a completion of  $H'_i$ , and  $\pi$  maps  $G$  to  $H'_i{}^c$ .  $\square$

We first check that  $G'$  has at most 3 exchangeable pairs w.r.t.  $(G', H')$ . For this it is sufficient to show that each exchangeable pair of  $G'$  is in  $Q$ . Let  $\{+p(u), -p(v)\}$  be an exchangeable pair of  $G'$ . As no  $G_i$  has any negative literal and the sets of relation names in the pairs  $(G_i, H_i)$  and in  $G$  are pairwise disjoint,  $\{+p(u), -p(v)\}$  is in  $G$ . Let  $\pi_1$  be a homomorphism from  $G'$  to a completion  $H'^{c1}$  of  $H'$  and  $\pi_2$  be a homomorphism from  $G'$  to a completion  $H'^{c2}$  of  $H'$  such that  $\pi_1(u) = \pi_2(v)$ . Let  $w = \pi_1(u) = \pi_2(v)$ . By Lemma 5, there exist an integer  $i$  in  $[0, q]$  and two completions  $H_i'^{c1}$  and  $H_i'^{c2}$  of  $H'_i$  such that  $w$  is in the part  $H'_i$  of  $H'^{c1}$  (and  $H'^{c2}$ ),  $H_i'^{c1}$  is a subgraph of the part  $H'_i$  of  $H'^{c1}$ ,  $H_i'^{c2}$  is a subgraph of the part  $H'_i$  of  $H'^{c2}$ ,  $\pi_1$  maps  $G$  to  $H_i'^{c1}$  and  $\pi_2$  maps  $G$  to  $H_i'^{c2}$ . Hence  $\{+p(u), -p(v)\}$  is an exchangeable pair of  $G'$  w.r.t.  $(G, H'_i)$ , and therefore is in  $Q$  by hypothesis on  $(G, H'_i)$ , which completes the proof that  $G'$  has at most 3 exchangeable pairs w.r.t.  $(G', H')$ .

It remains to prove that  $G'$  is entailed by  $H'$  if and only if there is some  $i$ ,  $0 \leq i \leq q$ , such that  $G_i$  is entailed by  $H_i$  and  $G$  is entailed by  $H'_i$ .

$\Rightarrow$ : By contradiction: we assume that  $G'$  is entailed by  $H'$  but that there is no  $i$  such that  $G_i$  is entailed by  $H_i$  and  $G$  is entailed by  $H'_i$ . Then for each  $i$  in  $[0, q]$  there is a completion  $H_i^c$  of  $H_i$  such that  $G_i$  cannot be mapped to  $H_i^c$  or there is a completion  $H_i'^c$  of  $H'_i$  such that  $G$  cannot be mapped to  $H_i'^c$ . Let  $H'^c$  be a completion of  $H'$  such that for each  $i$  in  $[0, q]$ , if  $H_i^c$  exists then  $H_i^c$  is a subgraph of the part  $H_i$  of  $H'^c$ , otherwise  $H_i'^c$  is a subgraph of the part  $H'_i$  of  $H'^c$ . As  $G'$  is entailed by  $H'$ , there is a homomorphism  $\pi$  from  $G'$  to  $H'^c$ . By Lemma 5, there exist an integer  $i$  in  $[0, q]$ , a completion  $H_i^d$  of  $H_i$  and a completion  $H_i'^d$  of  $H'_i$  such that  $H_i^d$  is a subgraph of the part  $H_i$  of  $H'^c$ ,  $H_i'^d$  is a subgraph of the part  $H'_i$  of  $H'^c$  and  $\pi$  maps  $G_i$  to  $H_i^d$  and  $G$  to  $H_i'^d$ . If some  $H_i^c$  as described above exists then  $H_i^c$  and  $H_i^d$  are completions of  $H_i$  that are both subsets of the part  $H_i$  of  $H'^c$ , hence  $H_i^c = H_i^d$  and  $\pi$  maps  $G_i$  to  $H_i^c$ , a contradiction. Otherwise  $H_i'^c$  exists, similarly  $H_i'^c = H_i'^d$  and  $\pi$  maps  $G$  to  $H_i'^c$ , a contradiction.

$\Leftarrow$ : We assume that there is some  $i$  such that  $G_i$  is entailed by  $H_i$  and  $G$  is entailed by  $H'_i$ . Let us show that  $G'$  is entailed by  $H'$ . Let  $H'^c$  be a completion of  $H'$ . Let us show that  $G'$  can be mapped to  $H'^c$ . Let  $H_i^c$  be the completion of  $H_i$  such that  $H_i^c$  is a subgraph of the part  $H_i$  of  $H'^c$ , and let  $\pi_1$  be a homomorphism from  $G_i$  to  $H_i^c$ . Let  $H_i'^c$  be the completion of  $H'_i$  such that  $H_i'^c$  is a subgraph of the part  $H'_i$  of  $H'^c$ , and let  $\pi_2$  be a homomorphism from  $G$  to  $H_i'^c$ . Then there is a homomorphism  $\pi$  from  $G'$  to  $H'$  extending  $\pi_1$  and  $\pi_2$ :  $\pi$  maps each  $v_j$  to  $v_j^i$  and each  $G_j$ , with  $j \neq i$ , to the part  $G_j$  inside  $A_i$  of  $H'^c$ .

We have thus built a polynomial reduction from Min-card-vertex cover compare to  $\text{ENTAILMENT}_3$ , which proves the theorem.  $\square$

## 4.5 When Homomorphism Checking is Polynomial

Checking the existence of a homomorphism becomes polynomial when  $G$  has a tree-like structure. More precisely, if  $G$  is seen as a graph, it is said to have a tree-like structure if it has a treewidth less than a fixed integer  $k$  (and in this case it corresponds to a formula of the  $k$ -variables fragment of FOL [KV00]); if  $G$  is seen as a hypergraph, with relation nodes becoming hyperedges, it has a tree-like structure if it has hypertreewidth at most a fixed integer  $k$  (and in this case it corresponds to a formula of the  $k$ -guarded fragment of FOL) [GLS01]. These particular cases are specially relevant in a query answering context, where  $G$  represents a query and  $H$  represents another query or a knowledge base composed of a set of facts. Indeed, a query generally has a simple structure.

Interestingly, our previous proofs also allow us to classify the complexity of  $\text{ENTAILMENT}$  and  $\text{ENTAILMENT}_k$  in the above special cases (except for  $k = 2$  for which the complexity in the general case is unknown):

**Theorem 8** *When  $G$  has bounded treewidth or hypertreewidth, the following complexity results hold:*

- $\text{ENTAILMENT}$  is co-NP-complete;
- $\text{ENTAILMENT}_0$  and  $\text{ENTAILMENT}_1$  (seen as promise problems) are in  $P$ ;
- $\text{ENTAILMENT}_k$  is co-NP-complete for any  $k \geq 3$ .

*Proof:*  $\text{ENTAILMENT}$  is in co-NP since a completion  $H^c$  of  $H$  to which  $G$  cannot be mapped is a polynomial certificate of the complementary problem,  $\text{NON-ENTAILMENT}$  (the size of  $H^c$  is polynomial in the size of  $H$  and checking that there is no homomorphism from  $G$  to  $H^c$  can be done in polynomial time since  $G$  has bounded treewidth or hypertreewidth). Its completeness for this complexity class follows from the proof of Th. 6, which shows that  $\text{ENTAILMENT}_3$  remains co-NP-hard when  $G$  has bounded treewidth (in the reduction, the graph  $G$  built is a tree). Hence,  $\text{ENTAILMENT}_k$  is also co-NP-complete for any  $k \geq 3$ . That  $\text{ENTAILMENT}_0$  is in  $P$  follows immediately from Prop. 8. To show that  $\text{ENTAILMENT}_1$  is also in  $P$ , let us consider Algorithm 1. Checking if there is an extensible homomorphism from  $G \setminus \{\sim p(u)\}$  to  $H$  can be done in polynomial time as follows.

We recall that there is an extensible homomorphism from  $G \setminus \{\sim p(u)\}$  to  $H$  if and only if there is a homomorphism  $\pi$  from  $G \setminus \{\sim p(u)\}$  to  $H$  such that  $\sim p(\pi(u))$  is not in  $H$ . Let  $s$  be the arity of  $p$ , let  $r$  be a new relation name, i.e., that does not occur in  $G$  and  $H$ , with arity  $s$ , let  $G' = (G \setminus \{\sim p(u)\}) + \{+r(u)\}$ , and let  $H'$  be the PG obtained from  $H$  by adding the literal  $+r(v)$  for each tuple  $v$  of  $s$  term nodes of  $H$  such that  $\sim p(v)$  is not in  $H$  (these tuples are in polynomial number since the arity of relation names is bounded by a constant). There is a homomorphism  $\pi$  from  $G \setminus \{\sim p(u)\}$  to  $H$  such that  $\sim p(\pi(u))$  is not in  $H$  if and only if there is a homomorphism from  $G'$  to  $H'$ . As  $G'$  is obtained from  $G$  by replacing relation name  $p$  by  $r$ ,  $G'$  has also bounded treewidth or hypertreewidth, hence the existence of a homomorphism from  $G'$  to  $H'$  can be checked in polynomial time. It follows that  $\text{ENTAILMENT}_1$  is in  $P$ .  $\square$

The previous theorem can be generalized to all cases where the existence of a homomorphism from  $G$  to  $H$  can be checked in polynomial time, provided, in the case of  $\text{ENTAILMENT}_1$ , that this property is preserved on the PGs  $G'$  and  $H'$  built from  $G$  and  $H$  in the previous proof.

## 4.6 Pieces

We will now take advantage of some simple graph properties to extend the previous results. First note that  $G$  is entailed by  $H$  if and only if each connected component

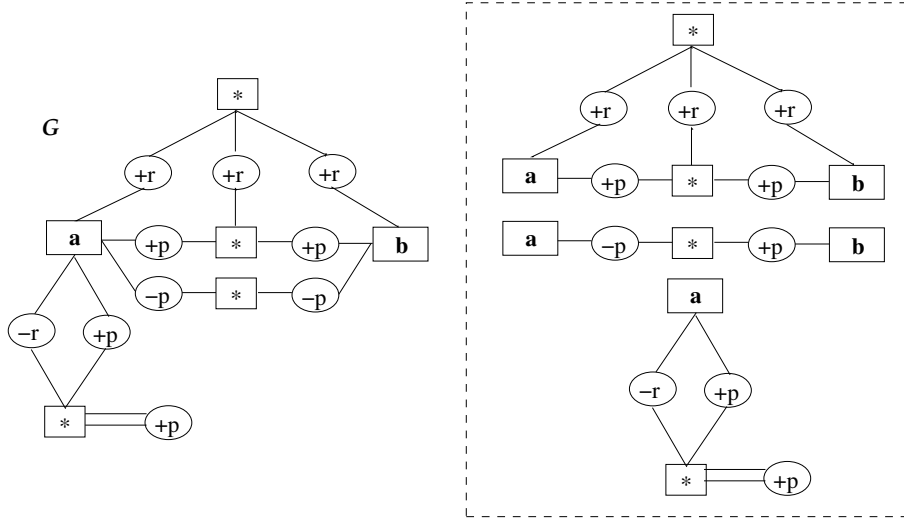

Figure 9: Pieces

of  $G$  is entailed by  $H$ . Second, by splitting constant nodes in  $G$  into several nodes (in this case  $G$  is no longer normal), we do not change the logical semantics of  $G$  and we preserve the existence of a homomorphism from  $G$  to any normal graph. Splitting a term node  $x$  into  $n$  nodes, according to a partition  $\{E_1, \dots, E_n\}$  of the edges incident to  $x$ , consists of deleting  $x$ , creating  $n$  term nodes  $x_1, \dots, x_n$  with the same label as  $x$ , and attaching to each  $x_i$  the edges in  $E_i$ , i.e., for each edge  $(x, j, r)$  in  $E_i$ , an edge  $(x_i, j, r)$  is created.

Let us define particular subgraphs that we call the *pieces* of  $G$  w.r.t. its constant nodes. Let  $\cong$  be the following equivalence relation: given two relation nodes  $r$  and  $s$  in  $G$ ,  $r \cong s$  if there is a path in  $G$  between  $r$  and  $s$  that does not go through a constant node, i.e., a path  $x_0(=r) \dots x_n(=s)$  such that, for  $0 < i < n$ ,  $x_i$  is not a constant node. The pieces of  $G$  are the subgraphs composed of the literals whose relation nodes are in the same equivalence class for  $\cong$ . This definition is extended to isolated term nodes by considering that each isolated node forms its own piece. See Figure 9, which shows a PG on the left and its pieces on the right. The pieces of  $G$  can be computed in linear time by a traversal of  $G$ .

**Proposition 13** *Let  $G$  and  $H$  be two PGs, with  $H$  being consistent.  $G$  is entailed by  $H$  if and only if each piece of  $G$  is entailed by  $H$ .*

Thus, in all previous complexity results,  $k$  can be seen as representing the maximum number of exchangeable pairs in a piece of  $G$  instead of in  $G$ .

The constant nodes in pieces of  $G$  can themselves be further split without any impact on the existence of a homomorphism from  $G$  to  $H$ . Some cycles in pieces can thus be broken, which may produce a graph decomposable into a tree (cf. Section 4.5).

See for instance Figure 9:  $G$  has 9 pairs of  $p$ -opposite literals, which may yield 9 pairs of exchangeable literals (depending on  $H$  and on edge labels in  $G$ , which are omitted in this figure); each piece of  $G$  has no  $p$ -opposite literals, *a fortiori* no exchangeable literals, thus to check whether  $G$  is entailed by  $H$ , one just has to check if each piece of  $G$  can be mapped to  $H$ . Furthermore, in this example, each piece of  $G$  can be transformed into a logically equivalent tree by splitting constant nodes, thus this instance of ENTAILMENT belongs to the polynomial cases.

## 5 Refining Completions and Exchangeability

In this section, we see how to reduce the set of literals added to  $H$  to obtain a completion of  $H$ , which in turn reduces the number of exchangeable pairs. We already restricted the set of literals added by defining the completion vocabulary w.r.t.  $(G, H)$ . The idea is that the obtained completions of  $H$  must satisfy the following fundamental property, denoted by *Completion Property*:  $G$  is entailed by  $H$  if and only if  $G$  can be mapped to each completion of  $H$ . By Th. 2, it is sufficient to add to  $H$  literals  $l$  such that at least one exchangeable literal in  $G$  can potentially be mapped to  $l$ . It follows that any literal  $l$  in a completion of  $H$  that is not in  $H$  and such that no exchangeable literal in  $G$  can be mapped to  $l$  can be removed from this completion. This restriction on completions of  $H$  induces a reduction of the set of homomorphisms from  $G$  to completions of  $H$ , and therefore of the set of exchangeable pairs, so that new literals in completions of  $H$  become useless and can be removed. This operation can be repeated, reducing both the set of literals added in completions of  $H$  and the set of exchangeable pairs, until stability is obtained. We first refine the notion of completion vocabulary, then we introduce exchangeable triples.

### 5.1 Completion Vocabulary

We defined the completion vocabulary w.r.t.  $(G, H)$  as the set of relation names with positive and negative occurrences in  $G$  and in  $H$ . We will give a simple process leading to an inclusion-smaller completion vocabulary (and therefore an inclusion-smaller set of exchangeable pairs). The idea is that if a relation name in the completion vocabulary does not appear in any exchangeable literal then it can be removed from the completion vocabulary  $\mathcal{R}$ , which in turn will reduce the set of

exchangeable literals w.r.t.  $(G, H, \mathcal{R})$ , i.e., defined with completions of  $H$  w.r.t.  $\mathcal{R}$ . Thus, we can successively restrict the completion vocabulary until it only contains relation names of exchangeable literals w.r.t.  $(G, H, \mathcal{R})$ . The refined completion vocabulary obtained by this process is denoted by  $\mathcal{R}(G, H)$ . We give a declarative definition of  $\mathcal{R}(G, H)$  and prove that it can be computed by the process explained above, which is formalized in Algorithm 3.

**Definition 10 (Refined completion vocabulary  $\mathcal{R}(G, H)$ )** *Let  $G$  and  $H$  be two PGs, with  $H$  being consistent, and let  $\mathcal{R}_0$  be the completion vocabulary w.r.t.  $(G, H)$ . The refined completion vocabulary w.r.t.  $(G, H)$ , denoted by  $\mathcal{R}(G, H)$ , is the inclusion-maximum subset  $\mathcal{R}$  of  $\mathcal{R}_0$  such that each relation name in  $\mathcal{R}$  appears in some exchangeable literal w.r.t.  $(G, H, \mathcal{R})$ .*

---

**Algorithm 3:**  $\mathcal{R}(G, H)$

---

**Data:**  $G$  and  $H$  two PGs, with  $H$  being consistent.

**Result:** the refined completion vocabulary  $\mathcal{R}(G, H)$ .

**begin**

    Let  $\mathcal{R}$  be the set of relation names that have both positive and negative occurrences in  $G$  and in  $H$

**repeat**

$\mathcal{R}_1 \leftarrow \mathcal{R}$

        Let  $\mathcal{R}$  be the set of relation names in exchangeable literals w.r.t.  $(G, H, \mathcal{R})$

**until**  $\mathcal{R} = \mathcal{R}_1$ ;

    return  $\mathcal{R}$

---

**Proposition 14** *Algorithm 3 is correct.*

*Proof:* Let  $\mathcal{R}^*$  be the set computed by Algorithm 3. Let us show that  $\mathcal{R}^* = \mathcal{R}(G, H)$ , i.e.,

- a) each relation name in  $\mathcal{R}^*$  appears in some exchangeable literal w.r.t.  $(G, H, \mathcal{R}^*)$ ,
- b) each subset  $\mathcal{R}'$  of  $\mathcal{R}_0$  such that each relation name in  $\mathcal{R}'$  appears in some exchangeable literal w.r.t.  $(G, H, \mathcal{R}')$  is a subset of  $\mathcal{R}^*$ .

Item a) follows from the exit condition of the repeat loop. Let us prove item b). Let  $\mathcal{R}'$  be a subset of  $\mathcal{R}_0$  such that each relation name in  $\mathcal{R}'$  appears in some exchangeable literal w.r.t.  $(G, H, \mathcal{R}')$ . Let us show that  $\mathcal{R}' \subseteq \mathcal{R}^*$ . It is sufficient to show that the inclusion  $\mathcal{R}' \subseteq \mathcal{R}$  is an invariant of the repeat loop. It holds at the initialization step since the initial value of  $\mathcal{R}$  is  $\mathcal{R}_0$  and  $\mathcal{R}'$  is a subset of  $\mathcal{R}_0$ .

We suppose that  $\mathcal{R}' \subseteq \mathcal{R}_i$ . Let us show that  $\mathcal{R}' \subseteq \mathcal{R}_{i+1}$ , where  $\mathcal{R}_{i+1}$  is the set obtained from  $\mathcal{R}_i$  after one iteration of the repeat loop. Let  $r \in \mathcal{R}'$ . Let us show that  $r \in \mathcal{R}_{i+1}$ . By hypothesis on  $\mathcal{R}'$ , as  $r \in \mathcal{R}'$ ,  $r$  appears in some exchangeable literal w.r.t.  $(G, H, \mathcal{R}')$ , which is also an exchangeable literal w.r.t.  $(G, H, \mathcal{R}_i)$  since  $\mathcal{R}' \subseteq \mathcal{R}_i$ , and therefore  $r \in \mathcal{R}_{i+1}$ .  $\square$

For instance, if  $G$  and  $H$  are the PGs shown in Figure 4,  $\mathcal{R}$  is initialized with  $\{p\}$  and is unchanged after one iteration of the repeat loop, thus  $\{p\}$  is the returned value; in that case  $\mathcal{R}(G, H)$  is equal to the completion vocabulary as previously defined (the refinement will be effective at the second step described in Section 5.2). In the general case,  $\mathcal{R}$  is initialized with the completion vocabulary w.r.t.  $(G, H)$  and strictly decreases at each iteration of the repeat loop, except for the last one where  $\mathcal{R}$  is unchanged.

Note that the number of iterations of the repeat loop is unbounded. Indeed, given any positive integer  $n$ , we can build two PGs  $G'$  and  $H'$  such that the execution of Algorithm 3 on  $G'$  and  $H'$  needs  $n + 2$  iterations. We define  $G'$  and  $H'$  from the PGs  $G$  and  $H$  shown in Figure 4 as follows. For each  $i$  in  $1, \dots, 2n - 1$ , let  $G_i$  be the PG obtained from  $G$  by adding the literals  $+r_i(x, y)$  and  $-r_{i+1}(y, z)$ .

For instance, if  $n = 2$ , we need 4 relation names  $r_1, r_2, r_3$  and  $r_4$ , and  $G_1$  (resp.  $G_2, G_3$ ) is obtained from  $G$  by adding literals  $+r_1(x, y)$  and  $-r_2(y, z)$  (resp.  $+r_2(x, y)$  and  $-r_3(y, z)$ ,  $+r_3(x, y)$  and  $-r_4(y, z)$ ). Note that none of these PGs  $G_i$  contains a relation node labeled with  $-r_1$  or with  $+r_{2n}$ . Let  $G'$  be the PG obtained from the disjoint union of copies of the PGs  $G_i$  for all  $i$  in  $1, \dots, 2n - 1$  by adding the literals  $-r_1(e, e)$  and  $+r_{2n}(e, e)$ . Let  $H_*$  be the PG obtained from  $G \setminus \{+p(x), -p(y), -p(z)\}$  by adding the literals  $+r_i(x, y)$  and  $-r_i(y, z)$  for all  $i$  in  $1, \dots, 2n$ . For instance, if  $n = 4$ , the literals of  $H_*$  are  $+r(x, y)$ ,  $+r(y, z)$ ,  $+r_1(x, y)$ ,  $+r_2(x, y)$ ,  $+r_3(x, y)$ ,  $+r_4(x, y)$ ,  $-r_1(y, z)$ ,  $-r_2(y, z)$ ,  $-r_3(y, z)$  and  $-r_4(y, z)$ . Let  $H'$  be the PG obtained from the disjoint union of  $H$  and  $H_*$  by adding the literals  $-r_1(e, e)$  and  $+r_{2n}(e, e)$ . The set  $\mathcal{R}$  is initialized with  $\{p, r_1, \dots, r_{2n}\}$ . Relation names  $r_1$  and  $r_{2n}$  are eliminated from  $\mathcal{R}$  at the first iteration of the repeat loop. As  $r_1$  and  $r_{2n}$  are no longer in  $\mathcal{R}$ ,  $r_2$  and  $r_{2n-1}$  are eliminated from  $\mathcal{R}$  at the second iteration, and so on. The set  $\mathcal{R}$  is reduced to  $\{p\}$  after iteration  $n$ , and becomes empty at iteration  $n + 1$ . As there is no homomorphism from  $G'$  to  $H'$ , we conclude that  $G'$  is not entailed by  $H'$ .

Let us show that all results of this paper still hold with this new definition of the completion vocabulary. It is sufficient to show that Th. 2 and Th. 3 and Prop. 12 still hold. For this, it is sufficient to show that completions w.r.t.  $\mathcal{R}(G, H)$  satisfy the Completion Property.

**Definition 11 (Completion Property for  $\mathcal{R}$ )** *Let  $G$  and  $H$  be two PGs, with  $H$  being consistent, and let  $\mathcal{R}$  be a set of relation names.  $\mathcal{R}$  satisfies the Completion*

Property w.r.t.  $(G, H)$  if the following equivalence holds:  $G$  is entailed by  $H$  if and only if  $G$  can be mapped to each completion of  $H$  w.r.t.  $\mathcal{R}$ .

**Proposition 15** *Let  $G$  and  $H$  be two PGs, with  $H$  being consistent.  $\mathcal{R}(G, H)$  satisfies the Completion Property w.r.t.  $(G, H)$ .*

*Proof:* Let  $P(\mathcal{R})$  be the property defined for any set  $\mathcal{R}$  of relation names by:

$P(\mathcal{R})$ :  $\mathcal{R}$  satisfies the Completion Property w.r.t.  $(G, H)$ .

Let us show that  $P(\mathcal{R})$  is an invariant of the repeat loop in Algorithm 3. By Property 3,  $P(\mathcal{R})$  holds at the initialization of the loop. We suppose that  $P(\mathcal{R})$  holds. Let  $\mathcal{R}'$  be the set of relation names in exchangeable literals w.r.t.  $(G, H, \mathcal{R})$ . Let us show that  $P(\mathcal{R}')$  holds. As  $P(\mathcal{R})$  holds and any completion of  $H$  w.r.t.  $\mathcal{R}'$  is a subgraph of a completion of  $H$  w.r.t.  $\mathcal{R}$ , it is sufficient to show that if  $G$  can be mapped to each completion of  $H$  w.r.t.  $\mathcal{R}$  then it can be mapped to each completion of  $H$  w.r.t.  $\mathcal{R}'$ . We suppose that  $G$  can be mapped to each completion of  $H$  w.r.t.  $\mathcal{R}$ , and let  $H^c$  be a completion of  $H$  w.r.t.  $\mathcal{R}'$ . Let us show that  $G$  can be mapped to  $H^c$ . Let  $H'$  be a completion of  $H$  w.r.t.  $\mathcal{R}$  containing  $H^c$ . As  $P(\mathcal{R})$  holds, Th. 2 (with completions and  $G_s$  being defined w.r.t.  $\mathcal{R}$ ) holds too. Let  $\pi$  be a homomorphism from  $G$  to  $H'$  mapping  $G_s$  to  $H$ . Each literal of  $G$  that is not mapped to a literal in  $H$  is exchangeable w.r.t.  $(G, H, \mathcal{R})$ , and therefore is mapped to a literal in  $H^c$  (since its relation name is in  $\mathcal{R}'$ ). Hence  $\pi$  maps  $G$  to  $H^c$ .  $\square$

It follows that all results of this paper still hold with  $\mathcal{R}(G, H)$  as completion vocabulary.

Note that any superset of  $\mathcal{R}(G, H)$  also satisfies the Completion Property. In practice, computing  $\mathcal{R}(G, H)$  may be too costly (remember that deciding whether  $G$  has an exchangeable pair is NP-complete), but it may be possible to identify some relation names that cannot be in any exchangeable literal. For instance, if the literal  $-r(e, e)$  is added to  $G$  and to  $H$  in the example of Figure 4,  $r$  becomes an element of the initial set  $\mathcal{R}$  in Algorithm 3, but it is easy to see that it is not the relation name of an exchangeable literal and can be removed from  $\mathcal{R}$ . Thus the repeat loop can be replaced by a while loop of the form:

**while** a relation name  $r$  that is in no exchangeable literal w.r.t.  $(G, H, \mathcal{R})$  can be “found” **do**

remove  $r$  from  $\mathcal{R}$

The while loop stops when no such relation name  $r$  can be detected, which does not mean that there is none. Hence, the obtained completion vocabulary may be only partially refined, but is in any case at least as good as the initial completion vocabulary.

## 5.2 Exchangeable Triples

So far we have restricted the relation names of literals added in completions of  $H$ , but not their arguments. We will now take these arguments into account in order to further reduce the set of added literals.

**Definition 12 (Triple w.r.t.  $(G, H)$ )** A triple w.r.t.  $(G, H)$  is a set  $\{+p(u), -p(v), w\}$  where  $+p(u)$  and  $-p(v)$  are  $p$ -opposite literals in  $G$  and  $w$  is an  $\text{arity}(p)$ -tuple of term nodes in  $H$  such that neither  $+p(w)$  nor  $-p(w)$  is a literal in  $H$ .

**Definition 13 (Completion w.r.t.  $\mathcal{T}$ )** Let  $G$  and  $H$  be two PGs, with  $H$  being consistent, and let  $\mathcal{T}$  be a set of triples w.r.t.  $(G, H)$ . A completion of  $H$  w.r.t.  $\mathcal{T}$  is a consistent PG obtained from  $H$  by adding, for each triple  $\{+p(u), -p(v), w\}$  in  $\mathcal{T}$ , either the literal  $+p(w)$  or  $-p(w)$ .

**Definition 14 (Exchangeable triple/pair w.r.t.  $(G, H, \mathcal{T})$ )** Let  $G$  and  $H$  be two PGs, with  $H$  being consistent, and let  $\mathcal{T}$  be a set of triples w.r.t.  $(G, H)$ . An exchangeable triple w.r.t.  $(G, H, \mathcal{T})$  is a triple  $\{+p(u), -p(v), w\}$  w.r.t.  $(G, H)$  such that there are two completions of  $H$  w.r.t.  $\mathcal{T}$ , say  $H_1$  and  $H_2$ , and two homomorphisms  $\pi_1$  and  $\pi_2$ , respectively from  $G$  to  $H_1$  and from  $G$  to  $H_2$  such that  $\pi_1(u) = \pi_2(v) = w$ . An exchangeable pair w.r.t.  $(G, H, \mathcal{T})$  is a pair  $\{+p(u), -p(v)\}$  such that for some  $w$ ,  $\{+p(u), -p(v), w\}$  is an exchangeable triple w.r.t.  $(G, H, \mathcal{T})$ .

The set  $\mathcal{T}(G, H)$  is defined similarly to  $\mathcal{R}(G, H)$  and computed by Algorithm 4.

**Definition 15 ( $\mathcal{T}(G, H)$ )** Let  $G$  and  $H$  be two PGs, with  $H$  being consistent, and let  $\mathcal{T}_0$  be the set of triples  $\{+p(u), -p(v), w\}$  w.r.t.  $(G, H)$  such that  $\{+p(u), -p(v)\}$  is an exchangeable pair w.r.t.  $(G, H, \mathcal{R}(G, H))$ .  $\mathcal{T}(G, H)$  is the inclusion-maximum subset  $\mathcal{T}$  of  $\mathcal{T}_0$  such that each triple in  $\mathcal{T}$  is an exchangeable triple w.r.t.  $(G, H, \mathcal{T})$ .

**Proposition 16** Algorithm 4 is correct.

*Proof:* It is similar to that of Prop. 14. □

Let us illustrate Algorithm 4 on the PGs  $G$  and  $H$  pictured in Figure 4.  $\mathcal{T}$  is initialized with  $\{\{+p(x), -p(y), b\}, \{+p(x), -p(y), d\}\}$ . It becomes  $\{\{+p(x), -p(y), b\}\}$  after the first iteration of the repeat loop, which reduces the set of completions of  $H$  w.r.t.  $\mathcal{T}$  to  $\{H + \{+p(b)\}, H + \{-p(b)\}\}$ . It becomes empty after the second iteration, since  $+p(x)$  can no longer be mapped to  $+p(b)$  by a homomorphism from  $G$  to a completion of  $H$  w.r.t.  $\mathcal{T}$ . Indeed, since  $d$  does not appear in any tuple

---

**Algorithm 4:**  $\mathcal{T}(G, H)$ 

---

**Data:**  $G$  and  $H$  two PGs, with  $H$  being consistent.

**Result:** the set  $\mathcal{T}(G, H)$ .

**begin**

    Let  $\mathcal{T}$  be the set of triples  $\{+p(u), -p(v), w\}$  w.r.t.  $(G, H)$  such that  $\{+p(u), -p(v)\}$  is an exchangeable pair w.r.t.  $(G, H, \mathcal{R}(G, H))$

**repeat**

$\mathcal{T}_1 \leftarrow \mathcal{T}$

        Let  $\mathcal{T}$  be the set of exchangeable triples w.r.t.  $(G, H, \mathcal{T})$

**until**  $\mathcal{T} = \mathcal{T}_1$ ;

    return  $\mathcal{T}$

---

of  $\mathcal{T}$ , no completion of  $H$  w.r.t.  $\mathcal{T}$  contains the literal  $-p(d)$ . Hence, there is no exchangeable pair w.r.t.  $(G, H, \mathcal{T}(G, H))$ , and since there is no homomorphism from  $G$  to  $H$ , it follows that  $G$  is not entailed by  $H$  (provided that Prop. 8 still holds, which is checked below).

We prove that all results of this paper still hold, similarly to the proofs for  $\mathcal{R}(G, H)$  by replacing  $\mathcal{R}(G, H)$  with  $\mathcal{T}(G, H)$ .

**Definition 16 (Completion Property for  $\mathcal{T}$ )** *Let  $G$  and  $H$  be two PGs, with  $H$  being consistent, and let  $\mathcal{T}$  be a set of triples w.r.t.  $(G, H)$ .  $\mathcal{T}$  satisfies the Completion Property w.r.t.  $(G, H)$  if the following equivalence holds:  $G$  is entailed by  $H$  if and only if  $G$  can be mapped to each completion of  $H$  w.r.t.  $\mathcal{T}$ .*

**Proposition 17** *Let  $G$  and  $H$  be two PGs, with  $H$  being consistent.  $\mathcal{T}(G, H)$  satisfies the Completion Property w.r.t.  $(G, H)$ .*

*Proof:* Let  $P(\mathcal{T})$  be the property defined for any set  $\mathcal{T}$  of triples w.r.t.  $(G, H)$  by:  $P(\mathcal{T})$ :  $\mathcal{T}$  satisfies the Completion Property w.r.t.  $(G, H)$ .

Let us show that  $P(\mathcal{T})$  is an invariant of the repeat loop in Algorithm 4.  $P(\mathcal{T})$  holds at the initialization of the loop since the completions of  $H$  w.r.t.  $\mathcal{T}$  are the completions of  $H$  w.r.t.  $\mathcal{R}(G, H)$ . We suppose that  $P(\mathcal{T})$  holds. Let  $\mathcal{T}'$  be the set of exchangeable triples w.r.t.  $(G, H, \mathcal{T})$ . Let us show that  $P(\mathcal{T}')$  holds. It is sufficient to show that if  $G$  can be mapped to each completion of  $H$  w.r.t.  $\mathcal{T}$  then it can be mapped to each completion of  $H$  w.r.t.  $\mathcal{T}'$ . We suppose that  $G$  can be mapped to each completion of  $H$  w.r.t.  $\mathcal{T}$ , and let  $H^c$  be a completion of  $H$  w.r.t.  $\mathcal{T}'$ . Let us show that  $G$  can be mapped to  $H^c$ . Let  $H'$  be a completion of  $H$  w.r.t.  $\mathcal{T}$  containing  $H^c$ . It is no longer sufficient to apply Th. 2 on  $H'$ , as we did for  $\mathcal{R}(G, H)$ , but we can use an argument similar to that used in the proof of Th. 2.

Let  $R$  be the set of literals  $l$  in  $H' \setminus H^c$  such that there is a homomorphism from  $G$  to  $H'$  mapping some literal of  $G$  to  $l$ .  $R$  is consistent since it is a set of literals in  $H'$ . Let  $H''$  be the completion of  $H$  w.r.t.  $\mathcal{T}$  obtained from  $H'$  by replacing every literal of  $R$  by its complementary literal, and let  $\pi$  be a homomorphism from  $G$  to  $H''$  (such a homomorphism exists by hypothesis on  $\mathcal{T}$ ). Let us show that  $\pi$  maps  $G$  to  $H^c$ . No literal of  $G$  can be mapped by  $\pi$  to the complementary literal of a literal  $l$  of  $R$  (otherwise this literal of  $G$  would be in an exchangeable triple w.r.t.  $(G, H, \mathcal{T})$ , so  $l$  would be a literal in  $H^c$ ). Thus  $\pi$  is a homomorphism from  $G$  to  $H'$ . Therefore, by definition of  $R$ , every literal of  $G$  is mapped by  $\pi$  to either  $H^c$  or  $R$ . However, as  $\pi$  is a homomorphism from  $G$  to  $H''$ , which contains no literal of  $R$ , no literal of  $G$  can be mapped to  $R$ , thus  $\pi$  maps  $G$  to  $H^c$ .  $\square$

Note that any superset of  $\mathcal{T}(G, H)$  also satisfies the Completion Property. In practice, we obtain a partially refined set of exchangeable triples by initializing  $\mathcal{T}$  with the set of triples  $\{+p(u), -p(v), w\}$  w.r.t.  $(G, H)$  such that  $p$  belongs to a partially refined completion vocabulary previously computed, and successively removing triples that can be recognized as non exchangeable. For instance, in the example of Figure 4 with (partially refined) completion vocabulary  $\{p\}$ ,  $\mathcal{T}$  initially contains the triples  $\{+p(x), -p(y), b\}$ ,  $\{+p(x), -p(y), d\}$ ,  $\{+p(x), -p(z), b\}$  and  $\{+p(x), -p(z), d\}$ . The three last triples are clearly non exchangeable, and removing them makes  $\{+p(x), -p(y), b\}$  clearly non exchangeable.

## 6 Related Work and Conclusion

Let us now relate the present complexity results to previous results obtained on the various forms of  $\text{FOL}(\exists, \wedge, \neg_a)$ -ENTAILMENT.

**Clause entailment.** When the logical language includes function symbols, clause entailment is undecidable [SS88], even if both clauses are Horn-clauses (i.e., with at most one positive literal) [MP92]. In [Got87], a sufficient condition under which a “subsumption test” (which can be identified with a homomorphism check) is complete is exhibited. Translated into ENTAILMENT, it says that if (1)  $h$  does not contain  $p$ -opposite literals, or (2)  $h$  is consistent and  $g$  does not contain  $p$ -opposite unifiable literals, then  $g$  is entailed by  $h$  if and only if  $g$  can be mapped to  $h$ . On the one hand, functions are allowed in this result, on the other hand if we exclude functions, we obtain particular cases of  $\text{ENTAILMENT}_0$ . To the best of our knowledge, the  $\Pi_2^P$ -completeness of clause entailment for clauses without functions had not been pointed out.

**Query containment.** In database query languages, function symbols are naturally excluded. The undecidability of query containment for several kinds of Datalog programs/queries has long been shown (see [Shm87] for the first results). Concerning the specific case of conjunctive queries with negation, the  $\Pi_2^P$ -completeness of the containment problem is claimed in several papers and proven in [FNTU07]<sup>11</sup>, with a reduction from the validity problem of quantified Boolean formulas of the form  $\forall^*\exists^*conj$ , where *conj* is a conjunction of 3-clauses. It was also proven in the framework of polarized graphs by Bagan (2004), with a reduction from a graph problem called Generalized Ramsey Number [SU02] and this proof is reported in [Mug07] [CM08]. In [LM07], it is proven that a homomorphism check is sufficient when *g* has no *dependent* literals, i.e., *p*-opposite literals  $l_1$  and  $l_2$  s.t.  $l_1$  and  $\bar{l}_2$  can be unified after a renaming of their common variables. We obtain again a particular case of  $\text{ENTAILMENT}_0$ . Notions close to our extensible homomorphism were used in algorithms for query containment checking in [WL03] and defined in [LM07].

As far as we know, the notion of exchangeable literals generalize all particular cases exhibited so far. As already mentioned, weaker criteria that yield an upper bound for the number of exchangeable pairs and can be checked in polynomial time can be used instead of exchangeability. In previous results, if the notion of an “exchangeable pair” is replaced by a “pair of *p*-opposite and unifiable literals”, these results are weaker but on the other hand any pair of term nodes can be checked in constant time. With this weaker condition, all complexity results are still new, except for  $\text{ENTAILMENT}_0$ .

**Conclusion.** In this paper, we have solved the main issues concerning the role of exchangeable literals in the complexity of  $\text{FOL}(\exists, \wedge, \neg_a)$ - $\text{ENTAILMENT}$ . We have shown that, as soon as the number *k* of exchangeable pairs is bounded, the complexity falls into  $P_{||}^{NP}$ , and becomes even NP-complete if  $k \leq 1$ . We have also shown that the problem is  $P_{||}^{NP}$ -complete for any *k* greater or equal to 3. To complete the picture, it would be interesting to determine its complexity for  $k = 2$ .

Let us mention that exchangeable literals can be exploited in algorithms solving  $\text{ENTAILMENT}$  for general  $\text{FOL}(\exists, \wedge, \neg_a)$  formulas. In [LM07] an algorithm is proposed for deciding inclusion of conjunctive queries with negation. Since queries are seen as PGs, this algorithm can be used without change for deciding on entailment in  $\text{FOL}(\exists, \wedge, \neg_a)$ . It explores a space of graphs leading from *H* to its

---

<sup>11</sup>Bibliographical note: several database papers wrongly mention that [LS93] proves the  $\Pi_2^P$ -completeness of the query inclusion problem for conjunctive queries with negation. More precisely, the  $\Pi_2^P$ -completeness result reported in [LS93] is for “conjunctive queries with order constraints” (and this result is due to van der Meyden). However, there is no straightforward proof that would translate this result into one for conjunctive queries with negation.

completions. This space is ordered as follows: given two graphs  $H_1$  and  $H_2$  in this space,  $H_2 \leq H_1$  if  $H_1$  is a subgraph of  $H_2$ . The question “is there a homomorphism from  $G$  to each completion  $H^c$ ” is reformulated as “is there a *covering set* of completions, i.e., a subset of incomparable graphs of this space  $\{H_1, \dots, H_k\}$  such that (1) there is a homomorphism from  $G$  to each  $H_i$ ; (2) for each  $H^c$  there is a  $H_i$  with  $H^c \leq H_i$ ”. This algorithm is then refined and experimentally evaluated on random instances in [BLM10]. Some special subgraphs of  $G$ , that are necessarily mapped to  $H$  if  $G$  is entailed by  $H$ , are used both in a filtering step (if one of these subgraphs cannot be mapped to  $H$ , then it can be concluded that  $G$  is not entailed by  $H$ ) and to guide the space exploration. These subgraphs are without  $p$ -opposite literals. They can be replaced by subgraphs without exchangeable pairs (see Th. 3). Moreover, the set of relation names considered in completions is restricted to relation names occurring both positively and negatively in  $G$  and  $H$  (see Prop. 3): this set can be further restricted to relation names occurring in exchangeable literals of  $G$  (Prop. 15), and the notion of completion can be further refined, using exchangeable triples (Prop. 17).

This paper is devoted to theoretical issues. As for further work, it would be interesting to study experimentally the practical interest of the obtained results. An issue is to study to what extent they can be used to improve the above mentioned algorithm, either on difficult problem instances (as in [BLM10]) or on real data. On real conjunctive queries with negation namely, the number of exchangeable literal pairs is expected to be null in many cases. A question is whether this number is upper bounded by a fixed value in practical query sets.

**Acknowledgements.** We thank the anonymous reviewers for their very constructive comments, in particular for the hint to the class  $P_{||}^{NP}$ , which allowed us to close the gap between NP/co-NP-hardness and  $P^{NP}$ , and for the clarification about promise problems.
