Abstract—This paper is dedicated to vision-based modeling and control of large-dimension parallel robots driven by inextensible cables of non-negligible mass. An instantaneous inverse kinematic model devoted to vision is introduced. This model relies on the specificities of a parabolic profile hefty cable modeling and on the resulting simplified static analysis. By means of a kinematic visual servoing method, computer vision is used in the feedback loop for easier control. According to the modeling derived in this paper, measurements that allow the implementation of this visual servoing consist of the mobile platform pose, the directions of the tangents to the cable curves at their drawing points and the cable tensions. The proposed visual servoing scheme will be applied to the control of a large parallel robot driven by eight cables. To this end, in order to obtain the aforementioned desired measurements, we plan to use a multi-camera setup together with force sensors.

I. INTRODUCTION

Parallel cable-driven robots are a particular type of parallel kinematic machines in which cables connect the base to the mobile platform [1], [2]. A 6-DOF parallel robot driven by six cables can be thought as a Gough-Stewart platform turned upside down with cables instead of prismatic actuators. When the cables are tensed and considered massless and inextensible, the kinematic modeling of Gough-Stewart platforms and of parallel cable-driven robots are very similar.

Visual servoing techniques [3], [4], [5] were applied to parallel robotics [6], [7], [8]. These applications rely on 3D visual servoing where the mobile platform pose is indirectly measured and used for regulation. To make control robust with respect to modeling errors, it was proposed to servo the leg edges [9] which improved the practical robustness by servoing the legs in the image. This method has been validated on a broad class of parallel robots [10].

Using a 3D pose kinematic visual servoing method, in which the mobile platform pose is used for regulation, the work reported in [11] confirmed that visual servoing techniques are a good alternative for the control of parallel cable robots. However, in [11], the cables are supposed to be massless. This assumption is invalid in the case of large-dimension cable robots [12] since the cables sag under their own weight. Assuming that the cable is inextensible and the sag relatively small, a simplified hefty cable modeling can be considered [13]. This simplified modeling describes the cable profile explicitly as a parabolic curve. Compared to the use of the elastic catenary [14], it leads in turn to a simplified (quasi) static analysis of large-dimension parallel cable robots [15].

The contribution of this paper is to extend the vision-based control proposed in [11] to large-dimension parallel cable robots. To this end, based on the aforementioned simplified hefty cable modeling, the instantaneous inverse kinematic model of large-dimension parallel cable robots is determined. This model turns out to be dependent on the pose of the mobile platform but also on the directions of the tangents to the cables at their drawing points and on the cable tensions.

The cable tensions can be obtained by means of force sensors. To estimate the mobile platform pose and the cable tangent directions, one can rely on vision. In the case of a large-dimension cable robot, it is obviously not conceivable to measure all the needed variables using a single perspective camera in front of the robot. Instead, we plan to use a multi-camera perception system. Firstly, several cameras observing visual targets attached to the mobile platform can provide an accurate pose estimation [16]. Using, e.g., four cameras provides a wide field of view and should always ensure the observation of significant part of the targets. Secondly, by locally observing each cable by means of a stereo pair (two cameras), 3D reconstruction yields the direction of the tangent to the cable at its drawing point. Indeed, a sagging cable can locally be approximated as a straight line segment.

This paper is organized as follows. Section II presents a simplified modeling of an inextensible cable of non-negligible mass. In Section III, the corresponding instantaneous inverse kinematic model of large-dimension parallel cable robots is derived. Section IV is dedicated to the vision-based control strategy. The presented method is validated...
on the simulator of the parallel CoGiRo cable robot in Section V. Conclusions are finally drawn in Section VI.

II. MODEL OF CABLE WITH NON-NEGLIGIBLE MASS DEVOTED TO VISION

Throughout the paper, the notations given in Table I will be used.

- $i = 1 ... k$ denotes the driving cables, where $k$ is the number of cables.
- Boldface characters denote vectors. Unit vectors are underlined.
- $\mathcal{F}_A$ is the frame associated to the mobile platform.
- $\mathcal{F}_B$ is a fixed reference frame associated to the robot.
- $\mathcal{F}_C$ is a mobile reference frame attached to the mobile platform.

Given $\mathbf{b}_i = \left( b_{ix}, b_{iy}, b_{iz} \right)^T$, the angle $\gamma_i$ can be computed as:

$$\gamma_i = \tan^{-1} \left( \frac{b_{iy}}{b_{ix}} \right)$$  \hspace{1cm} (1)

A simplified modeling of an inextensible hefty cable [13] is used in this paper. This model is obtained from the elastic catenary modeling [14], [15]. It results in a parabolic cable profile equation, expressed in frame $\mathcal{F}_{Ai}$, which is given by:

$$z_i = - \frac{\rho_i g L_i}{2 A_i B_{ix} A_i B_{ix}^2} x_i (A_i B_{ix} - x_i) + x_i \tan(\beta_{0i})$$  \hspace{1cm} (2)

where $x_i$ and $z_i$ are the coordinates in frame $\mathcal{F}_{Ai}$ of cable point $S_i$ (see Fig. 2).

The angle $\beta_{0i}$ between $\mathbf{u}_i$ and $\mathbf{x}_{Ai}$ (Fig. 2) can be written as:

$$\beta_{0i} = \tan^{-1} \left( \frac{A_i B_{ix}}{A_i B_{ix}^2} \right)$$  \hspace{1cm} (3)

A. Tangents to the cable profile

The slope of the tangents to the cable profile (Eq. (2)) at points $B_i$ and $A_i$ (see Fig. 2) can be computed using:

$$\frac{dz_i}{dx_i} (x_i = B_{ix}) = \tan(\beta_i)$$  \hspace{1cm} and  \hspace{1cm} $$\frac{dz_i}{dx_i} (x_i = 0) = \tan(\alpha_i)$$  \hspace{1cm} respectively.

According to (2), one can write:

$$\tan(\beta_i) = \tan(\beta_{0i}) + \frac{\rho_i g L_i}{2 A_i B_{ix} A_i B_{ix}^2}$$

$$\tan(\alpha_i) = \tan(\beta_{0i}) - \frac{\rho_i g L_i}{2 A_i B_{ix} A_i B_{ix}^2}$$  \hspace{1cm} (4)

Since $A_i \partial_{Aix} = -A_i \partial_{Bix}$ (as the only external loading applied to the cable between $A_i$ and $B_i$ is the cable weight) and introducing $\mathbf{u}_i = \left( \cos(\beta_{0i}) \ 0 \ \sin(\beta_{0i}) \right)^T$, one can compute:

$$A_i \partial_{B_i} = A_i \partial_{Aix} A_i \mathbf{u}_i + \frac{\rho_i g L_i}{2} A_i \mathbf{z}_{Ai}$$

$$A_i \partial_{A_i} = -A_i \partial_{Bix} A_i \mathbf{u}_i + \frac{\rho_i g L_i}{2} A_i \mathbf{z}_{Ai}$$  \hspace{1cm} (5)

It is important to note that the last equation can be expressed in any Euclidean reference frame. In the general case, we can write:

$$\partial_{B_i} = \mathbf{u}_{Bi} + \mathbf{u}_{pi}$$

$$\partial_{A_i} = \mathbf{u}_{Ai} - \mathbf{u}_{pi}$$  \hspace{1cm} (6)

where $\mathbf{u}_i = \frac{A_i \partial_{Aix}}{\cos(\beta_{0i})} \mathbf{u}_i$, $\mathbf{u}_{pi} = \frac{\rho_i g L_i}{2} \mathbf{z}_{Ai}$.

B. Inverse kinematics

The inverse kinematics gives the length of each cable for a given pose of the platform. Using the cable profile of Eq. (2), one can compute the cable length by integrating a cable length element [15]:

\[ l_i = \int_{0}^{A_i B_i} \sqrt{1 + \left( \frac{dz}{dx} \right)^2} \, dx \]

\[ = A_i B_i c_i \left( k_1 - c_2 k_2 + \log(c_1 + k_1) \right) \tag{7} \]

where \( r_i = \frac{p_0 B_i}{B_i \rho}, \quad k_1 = \tan(\beta_0_i) + \frac{p_0}{r_i}, \quad k_2 = \tan(\beta_0_i) - \frac{p_0}{r_i}, \quad c_1 = \sqrt{1 + k_1^2}, \quad \text{and} \quad c_2 = \sqrt{1 + k_2^2}. \]

III. VISION-BASED KINEMATICS

The instantaneous inverse kinematic model of a parallel robot driven by cables relates the Cartesian velocity \( \tau_c \) of the mobile platform to the time derivative \( \dot{\mathbf{i}} = \left( \dot{l}_1, \ldots, \dot{l}_k \right)^T \) of cable length vector. The Cartesian velocity of the mobile platform expressed in a fixed reference \( f_f \) is \( \dot{\mathbf{r}}_c = f_{\tau_c f} = \left( f_{\nu_{c f}}, f_{\Omega_{c f}} \right)^T. \)

The time derivative of (7) provides:

\[ \dot{l}_i = N_i \left( \frac{A_i B_i}{L_i}, \frac{A_i \dot{\vartheta}_{Bi x}}{L_i} \right) \tag{8} \]

where

- \( N_i = \left( N_{i1}, 0, N_{i2}, N_{i3}, N_{i4} \right) \)

- \( N_{i1} = \frac{r_i}{r_i - (c_1 - c_2) A_i B_i}, \quad N_{i2} = \frac{c_1 - c_2}{r_i (c_1 + c_2) A_i B_i}, \quad N_{i3} = \frac{2 l_i}{2 l_i + (c_1 + c_2) A_i B_i}, \quad \text{and} \quad N_{i4} = \frac{2 l_i}{2 A_i \vartheta_{Bi x}}. \)

The terms \( A_i \dot{\mathbf{B}}_i, \dot{\mathbf{L}}_i \) and \( A_i \dot{\vartheta}_{Bi x} \) in (8) can be expressed as the product of their associated interaction matrices \( D_{Bi}, D_{Li} \) and \( D_{si} \) by \( f_{\tau_c} \), so that (8) becomes:

\[ \dot{l}_i = D_{li} f_{\tau_c} \tag{9} \]

where \( D_{li} = N_i \left( \frac{D_{Bi}}{D_{Li}}, \frac{D_{Bi}}{D_{Li}} \right), \) the expression of \( D_{Bi}, D_{Li} \) and \( D_{si} \) being derived in the next subsections.

In the case of an inextensible cable, time derivative of the motorized joint angle vector \( \mathbf{q} \) of the robot is linearly related to the time derivative of the cable length vector and can be computed as \( \dot{\mathbf{q}} = \frac{1}{r_c} \dot{\mathbf{l}}, \) where \( r_c \) is the radius of the drums collecting the cables. Therefore, the instantaneous inverse kinematic model associated with the motorized joint angle vector \( \mathbf{q} \) can be written as:

\[ \dot{\mathbf{q}} = \frac{1}{r_c} D_a f_{\tau_c} \tag{10} \]

where \( D_a \) is the compound matrix containing the matrices \( D_{ai}, i = 1 \ldots k. \)

A. Expression of \( D_{Li} \)

According, e.g., to [2], [11], the expressions of the time derivatives of \( \dot{l}_i \) and \( f_{\mathbf{u}_i} \) (case of an inextensible and massless cable) are:

\[ \dot{l}_i = D_{Li} f_{\tau_c} \tag{11} \]

where \( D_{Li} = f_{\mathbf{u}_i}^T \left( \mathbf{I}_3 - [-\mathbf{R}_e^* \mathbf{B}_i]_x \right) \), and:

\[ f_{\mathbf{u}_i} = D_{ui} f_{\tau_c} \tag{12} \]

where \( D_{ui} = \frac{1}{r_i} (I_3 - f_{\mathbf{u}_i}^T f_{\mathbf{u}_i}) \left( \mathbf{I}_3 - [-\mathbf{R}_e^* \mathbf{B}_i]_x \right). \)

B. Expression of \( D_{Bi} \)

1) Angular velocity of \( f_{\mathbf{A}_i} \) expressed in \( f_f \):

The time derivative of (1) gives:

\[ \dot{\gamma}_i = D_{0i} f_{\mathbf{u}_i} = D_{0i} f_{\mathbf{R}_f} f_{\mathbf{u}_i} \tag{13} \]

where \( D_{0i} = \frac{1}{u_{ii}^2 + u_{ix}^2} (-b_{uiy}, b_{uix}, 0). \)

Taking into account the fact that \( f_{\mathbf{z}_0} = f_{\mathbf{A}_i} \) and according to (12), the angular velocity of \( f_{\mathbf{A}_i} \) is defined by:

\[ f_{\Omega_{Ai}} = D_{li} f_{\tau_c} \tag{14} \]

where \( D_{li} = f_{\mathbf{z}_0} D_{0i} f_{\mathbf{R}_f} D_{ui}. \)

2) Inverse kinematic model associated with \( A_i B_i \):

The time derivative of \( B_i \), with respect to the fixed reference frame \( f_f \), is:

\[ f_{\dot{B}_i} = D_{Bi f} f_{\tau_c} \tag{15} \]

where \( D_{Bi f} = ( \mathbf{I}_3 - [-\mathbf{R}_e^* \mathbf{B}_i]_x ). \)

In the local frame \( f_{\mathbf{A}_i} \), the velocity of \( A_i B_i \) has the following form:

\[ A_i \dot{\mathbf{B}}_i = A_i \mathbf{R}_f^* [f_{\mathbf{A}_i} f_{\mathbf{B}_i}] \times f_{\Omega_{Ai}} + A_i \mathbf{R}_f^* f_{\dot{B}_i} \tag{16} \]

Substituting (14) and (15) in (16) gives:

\[ A_i \dot{\mathbf{B}}_i = D_{Bi f} f_{\tau_c} \tag{17} \]

where \( D_{Bi f} = A_i \mathbf{R}_f^* [f_{\mathbf{A}_i} f_{\mathbf{B}_i}] \times f_{\Omega_{Ai}} + D_{Bi f} \).

C. Expression of \( D_{si} \)

1) Mobile platform static equilibrium:

One can write the force applied at point \( \mathbf{B}_i \) by the cable to the platform as (see Eq. (6)):

\[ f_{\mathbf{f}_{Bi}} = -f_{\vartheta_{Bi}} = -f_{\mathbf{u}_{Bi}} \tag{18} \]

where \( \vartheta_{Bi} \geq 0 \) since a cable can only pull on the platform. Assuming that the moment of \( f_{\mathbf{f}_{Bi}} \) at point \( \mathbf{B}_i \) is \( \eta_{Bi} = 0, \) the wrench applied by cable \( i \) at the reference point \( \mathbf{E}_i \) expressed in \( f_f \), is:

\[ f_{\mathbf{\eta}_i} = \left( \begin{array}{c} f_{\mathbf{f}_{Bi}} \\ f_{\mathbf{E}_i} \times f_{\mathbf{f}_{Bi}} \end{array} \right) \tag{19} \]

According to the mobile platform equilibrium, one can write the relationship between the external wrenches \( f_{\mathbf{\eta}_{Fe}} \) and cable wrenches as:

\[ f_{\mathbf{\eta}_{Fe}} + \sum_{i=1}^{k} (f_{\mathbf{\eta}_i}) = 0 \tag{20} \]

Assuming that \( f_{\mathbf{\eta}_{Fe}} = 0 \) (a pseudo-static case), the time derivative of (20) leads to:

\[ \sum_{i=1}^{k} (f_{\dot{\mathbf{\eta}}}_i) = 0 \tag{21} \]
where
\[
\dot{t}_i = -\left( \frac{1}{f} \dot{u}_{Bi} \right) \left( f_{EBi} \times \dot{u}_{Bi} + f_{EBi} \times f_{uBi} \right) \quad (22)
\]

At this time, we can write:
\[
f_{EBi} = D_{EBi} \dot{\tau}_c \quad (23)
\]

where \( D_{EBi} = \left( 0 \right)_{3 \times} \left[ f \mathbf{R}_{e} \mathbf{B}_i \times \mathbf{R}_{e} \right] \).

Therefore (22) becomes:
\[
\dot{t}_i = -\left( \frac{1}{f} \dot{u}_{Bi} \right) \left( -[f_{uBi}]_{x} D_{EBi} \dot{\tau}_c + [f_{EBi}] \times \dot{u}_{Bi} \right) \quad (24)
\]

2) **Time derivative of \( f_{uBi} \):**

The time derivative of (6), expressed in the fixed frame \( \mathcal{F}_f \), gives:
\[
f_{uBi} = f_{uBi} + f \dot{\mathbf{u}}_{Bi} \quad (25)
\]

Using (3), the time derivative of \( \beta_{Bi} \) can be computed as:
\[
\dot{\beta}_{Bi} = \frac{\cos(\beta_{0i})^2}{A_{Bi}} \left( -A_{Bi} \mathbf{B}_1 \mathbf{B}_i \cos(\beta_{0i}) \right) \dot{A}_{Bi} \quad (26)
\]

Thus, according to (26) and to the expression of \( \dot{u}_i \) given in Section II-A, the time derivative of \( f_{uBi} \) is:
\[
f_{uBi} = D_{ui1} \dot{\tau}_c + D_{ui2} \dot{A}_{Bi} \dot{\theta}_{Bix} \quad (28)
\]

where
\[
\begin{align*}
D_{ui1} &= (D_{f1} D_{Bi1} + \frac{A_{i} \dot{\theta}_{Bix}}{\cos(\beta_{0i})} D_{u1i}) \\
D_{f1} &= \frac{A_{i} \dot{\theta}_{Bix} \sin(\beta_{0i})}{A_{Bi} \cos(\beta_{0i})} \left( -A_{Bi} \mathbf{B}_1 \mathbf{B}_i \cos(\beta_{0i}) \right) \\
D_{ui2} &= \frac{A_{i} \dot{\theta}_{Bix}}{A_{Bi} \cos(\beta_{0i})} \quad (30)
\end{align*}
\]

Then, using (11), the time derivative of \( f_{uBi} \) is:
\[
f_{uBi} = D_{ui1} f_{\tau}_c + D_{ui2} \dot{A}_{Bi} \dot{\theta}_{Bix} \quad (31)
\]

3) **Expression of \( \dot{A}_{Bi} \dot{\theta}_{Bix} \):**

Using (30) and (24), one can deduce:
\[
\dot{A}_{Bi} \dot{\theta}_{Bix} = -D_{ui1} \dot{f}_{\tau}_c + D_{ui2} \dot{A}_{Bi} \dot{\theta}_{Bix} \quad (32)
\]

where
\[
\begin{align*}
D_{ui1} &= \left( -f_{uBi} \right)_{x} D_{EBi} \times \left( \dot{f}_{uBi} \right)_{x} D_{u1i} \\
D_{ui2} &= \left( [f_{EBi}] \times \dot{f}_{uBi} \right) \times D_{u1i}
\end{align*}
\]

Equ. (21) becomes:
\[
\sum_{i=1}^{k} \left( D_{ui1} \right) \dot{f}_{\tau}_c + D_{ui2} \dot{A}_{Bi} \dot{\theta}_{Bix} = 0 \quad (32)
\]

where
\[
D_{ui1} = \left( -f_{uBi} \right)_{x} D_{EBi} \times \left( \dot{f}_{uBi} \right)_{x} D_{u1i}
\]

\[
D_{ui2} = \left( [f_{EBi}] \times \dot{f}_{uBi} \right) \times D_{u1i}
\]

\[
\begin{align*}
\dot{\tau}_c &= \sum_{i=1}^{k} \left( D_{ui1} \right) \dot{f}_{\tau}_c + D_{ui2} \dot{A}_{Bi} \dot{\theta}_{Bix} \quad (33)
\end{align*}
\]

where \( D_{ui1} = -f_{uBi} \mathbf{R}_{Bx} \) and \( D_{ui2} = \mathbf{R}_{Bx} \times f_{uBi} \).

Finally, one can deduce:
\[
\dot{\tau}_c = \sum_{i=1}^{k} \left( D_{ui1} \right) \dot{f}_{\tau}_c + D_{ui2} \dot{A}_{Bi} \dot{\theta}_{Bix} \quad (33)
\]

where \( D_{ui1} = -f_{uBi} \mathbf{R}_{Bx} \) and \( D_{ui2} = \mathbf{R}_{Bx} \times f_{uBi} \).

IV. VISION-BASED CONTROL

A. Control

Visual servoing is based on the so-called interaction matrix \( \mathbf{L}_s \) which relates the instantaneous relative Cartesian motion \( \mathbf{r} \) between the mobile platform and the scene to the time derivative of the vector \( s \) of the visual primitives used for regulation [17] (\( \dot{s} = \mathbf{L}_s \mathbf{r} \)). According to the nature of the visual primitives, there exist many visual servoing techniques ranging from position-based visual servoing [18], [19] to image-based visual servoing [4], [20], most of them being based on point features. One can also find other visual primitives such as lines [21] or image moments [22].

As the instantaneous inverse kinematic model (10) depends on the platform pose, we choose position-based visual servoing in the 3D pose form [18], [19], [23]: \( s = ( s_t \ s_w )^T \).

Consider \( \mathcal{F}_m \) and \( \mathcal{F}_m^* \) the current and the desired mobile frame locations, respectively. \( s_t = m_{t_m} \) is the translation error between \( \mathcal{F}_m \) and \( \mathcal{F}_m^* \) and \( s_w = \mathbf{w}_\theta \), where \( \mathbf{w} \) is the axis and \( \theta \) is the angle of the rotation matrix \( m_{R_m} \).

The interaction matrix associated to the pose can be written as [23], [24]:
\[
\mathbf{L}_s = \begin{pmatrix} -
I_3 & \left[ m_{t_m} \right] \times \\
0_3 & -
L_w 
\end{pmatrix} \quad (35)
\]

where
\[
\begin{align*}
\mathbf{L}_w &= \mathbf{I}_3 - \frac{1}{\theta} \left[ \mathbf{w} \right] \times + \left( 1 - \frac{\sin(\theta)}{\sin^2(\theta/2)} \right) \left[ \mathbf{w} \right] \times \\
\sin(\theta) &= \frac{\sin(\theta)}{\theta} \text{ and } m_{T_m} = \frac{m_{T_{m/m^*}}}{m_{T_{m/f}}}
\end{align*}
\]

Fig. 3. Visual servoing of a cable-driven parallel robot

To regulate the error between the current primitive vector \( s \) and the desired one \( s^* = 0 \), one can consider the exponential decay \( s = -\lambda s \). The vision-based control (Fig. 3) can then be expressed as:
\[
m_{T_m} = -\lambda \mathbf{L}_s^+ \mathbf{s} \quad (36)
\]
With $f_{te} = D_t \tau_m$ and using (36), (10) becomes:

$$
\dot{q} = m D_m \tau_m = -\lambda_m D_m \hat{L}_s + s
$$

(37)

where $D_t = \left( f_{Rm} \ f_{Rm}^{[m-t]} \right)$ and $m D_m = \frac{1}{2} D_s D_s$.

B. Examples of measured variables and parameters to identify

Note that the instantaneous inverse kinematic model (10) depends on $T_m$, the rigid transformation between the mobile and the fixed frame which defines the pose of the platform. It depends also on the tangents $f_u_{Ai}$ to the cables at their drawing points, which we plan to measure by vision, and on some constant (calibration) parameters $(f_{A_i}, f_{B_i}, f_{T_i})$. The transformations $m T_e$ and $m T_b$. Let us also note that only information from the vision sensor are used to define the interaction matrix given in (35).

In the instantaneous inverse kinematic model (10), we need also the angles $d \beta_i$ (See Fig. 2 for the definition of these angles), in the desired setup is not the only possible one but has been selected based on practical constraints. All kinematic parameters are expressed in a reference frame $\mathcal{F}_f = \mathcal{F}_{cj}$ attached to the base frame.

![Fig. 4. A simulated CoGiRo robot.](image)

In the instantaneous inverse kinematic model (10), we need to define the rotation $A_i R_b$, which depends on the angle $\gamma_i$ as shown in (1). This angle can also be computed using $\gamma_i = \tan^{-1}(\frac{\mathbf{u}_{Al}}{\|\mathbf{u}_{Al}\|})$, where $\mathbf{u}_{Al} = \mathbf{R}_f \mathbf{u}_{Al}$. We need also the angle $\beta_0i$ defined in (3). This angle can be computed using the following expressions of the attachment point $B_i$:

$$
\begin{cases}
A_i B_i = f R_m (f R_f B_i + b f_t) + A_i t_m \\
f B_i = f R_m m B_i + f t_m
\end{cases}
$$

(38)

where $f B_i$ and $f t_m$ can be measured by vision and $m B_i$ is a constant parameter.

The instantaneous inverse kinematic model (10) depends also on the length $L_i = \| f A_i B_i \|$ of cable $i$ supposed to be massless (straight line) and on the component $A_i \dot{g}_{Bi}$ of the force applied to the cable at its attachment point $B_i$.

Using (6), the non-unit vector $f u_{Bi}$ can be computed as:

$$
f u_{Bi} = f \dot{g}_{Bi} = -A_i \dot{g}_{Ai} f u_{Ai} + \rho_0 g L_i f Z_{Ai}
$$

(39)

where $f Z_{Ai} = f R_h f Z_{Ai}$ and $A_i \dot{g}_{Ai}$ is given by a tension sensor (possibly indirectly).

Consequently, using $A_i \dot{g}_{Bi} = A_i R_h f f \dot{g}_{Bi}$, one can compute $A_i \dot{g}_{Bix} = A_i f X_i A_i \dot{g}_{Bi}$.

V. Simulation Results

The vision-based control strategy introduced in the previous section is validated by means of a CoGiRo cable- driven parallel robot simulation (Fig. 4). CoGiRo is a 6-DOF large-dimensional parallel cable-driven robot. It has a moving platform (end-effector) connected to a fixed base by 8 driving cables of varying lengths $l_i$, $i = 1 \ldots 8$ (k = 8). Each cable (Fig. 4) is attached to the moving platform at point $B_i$ and extends from the base at point $A_i$.

In the simulation, $b E = (0, 0, 0)^T m$ and $(\theta_x, \theta_y, \theta_z)^T = (0, 0, 0)^T$ defines the initial configuration of the CoGiRo platform simulation. The desired one (Fig. 5) is $b E^* = (2, 1, 1)^T m$ and $(\theta_x^*, \theta_y^*, \theta_z^*)^T = (0, 10^\circ, 20^\circ)^T$.

In a first simulation, we choose three geometric characteristic cases (dimensions: width x length x height) of the CoGiRo robot. Tab. II presents the angles $d \beta_i = \beta_i - \beta_0i$ (See Fig. 2 for the definition of these angles), in the desired position. $d \beta_i$ increases according to the dimensions of the robot which confirms that the cables can not be considered as a straight line segments, in the case of a large-dimension parallel cable-driven robots.

In a second simulation, we choose the dimensions of the real CoGiRo robot (10.8 x 14 x 5.5 m (width x length x height)). To show the robustness of the proposed vision-based control, we added noise to the estimation of the Cartesian pose $f T_m$. We define at each time a sample random rotation axis and a positive rotation angle with maximal amplitude of $5^\circ$. We also added noise to the rotation angles, with amplitude of $2^\circ$. Assuming that the directions of the tangents to the cable curves at their drawing points is essentially a unit vector, the added noise can be modeled by a rotation of the unit vector in each direction. Consequently, we define at each time a sample random rotation axis and a positive rotation angle with maximal amplitude of $0.2^\circ$.

Fig. 6 shows a potentially good robustness. As expected, the Cartesian errors converge exponentially to final errors displayed in Table III, with a perfect decoupling. The 3D trajectory of the mobile platform (Fig. 7) is linear in the fixed reference frame $\mathcal{F}_f = \mathcal{F}_{cj}$, which confirms the properties of the 3D pose visual servoing.

Table III presents mean values and standard deviations of the final error vector norm. These accuracy results are deemed satisfactory enough for such a large-dimension parallel robot.
In this paper, we have introduced an instantaneous inverse kinematic model of large-dimension cable-driven parallel robots. This model relies on a simplified model of an inextensible hefty cable in which the cable profile is considered to be a parabolic curve. It can be used to compute an explicit expression of each cable tangent and to compute a partially decoupled inverse kinematic problem. We have shown that the proposed instantaneous inverse kinematic model depends on the mobile platform pose, the cable tangent directions and the cable tensions. A multi-camera setup should allow us to measure the pose of a visual target attached to the mobile platform and the direction of the cable tangents. The cable tensions are measured by means of force sensors. Computer vision can then be used in the feedback loop by using of a 3D pose kinematic visual servoing method. This latter has been validated on the simulator of a large parallel cable robot.

The next step in our work is thus to implement the vision-based control strategy proposed in this paper on a real parallel CoGiRo cable robot.

VI. CONCLUSION

In this paper, we have introduced an instantaneous inverse kinematic model of large-dimension cable-driven parallel robots. This model relies on a simplified model of an inextensible hefty cable in which the cable profile is considered to be a parabolic curve. It can be used to compute an explicit expression of each cable tangent and to compute a partially decoupled inverse kinematic problem. We have shown that the proposed instantaneous inverse kinematic model depends on the mobile platform pose, the cable tangent directions and the cable tensions. A multi-camera setup should allow us to measure the pose of a visual target attached to the mobile platform and the direction of the cable tangents. The cable tensions are measured by means of force sensors. Computer vision can then be used in the feedback loop by using of a 3D pose kinematic visual servoing method. This latter has been validated on the simulator of a large parallel cable robot.

The next step in our work is thus to implement the vision-based control strategy proposed in this paper on a real parallel CoGiRo cable robot.

VII. ACKNOWLEDGMENT

This work was supported by the ANR (grant 2009 SEGI 018, CoGiRo project).
