HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Covering and packing pumpkin models

Abstract
Let $\theta_r$ (the $r$-pumpkin) be the multi-graph containing two vertices and $r$ parallel edges between them. We say that a graph is a $\theta_r$-model if it can be transformed into $\theta_r$ after a (possibly empty) sequence of contractions. We prove that there is a function $g: \mathbb{N} \rightarrow \mathbb{N}$ such that, for every two positive integers $k$ and $q$, if $G$ is a $K_q$-minor-free graph, then either $G$ contains a set of $k$ vertex-disjoint subgraphs (a $\theta_r$-model-vertex-packing) each isomorphic to a $\theta_r$-model or a set of $g(r) \cdot \log q \cdot k$ vertices (a $\theta_r$-model-vertex-cover) meeting all subgraphs of $G$ that are isomorphic to a $\theta_r$-model. Our results imply a $O(\log OPT)$-approximation for the maximum (minimum) size of a $\theta_r$-model packing ($\theta_r$-model covering) of a graph $G$.

1 Introduction

The Erdős–Pósa theorem, proved in 1965 [6], revealed the following min-max relation between coverings and packings of cycles in graphs: every graph that does not contain $k$ disjoint cycles, contains a set of $O(k \log k)$ vertices meeting all its cycles. They also proved that this result is tight by giving graph contractions where the $O(k \log k)$ bound is realized. Various extensions of this result, referring to different notions of packing and covering, attracted the attention of many researchers in modern Graph Theory (see [1,10]).

A model of a graph $H$ is any graph that can be contracted to $H$. Given two graphs $H$ and $G$, we denote by $\text{pack}_H(G)$ the maximum number of vertex-disjoint models of $H$ in $G$. We also denote by $\text{cover}_H(G)$ the minimum number of vertices that intersect all minor models of $H$ in $G$. We are interested in graphs $H$ for which the following relation holds:

\[
\text{for every } G, \text{ if } \text{pack}_H(G) \leq k \text{ then } \text{cover}_H(G) = O(k \cdot \log k) \tag{1}
\]

Clearly if $\theta_2$ is the graph with two vertices and two edges between them, then Relation (1) holds because of the Erdős–Pósa theorem. In the most general case, Robertson and Seymour proved [13] that if $H$ is planar, then for every graph $G$, $\text{cover}_H(G)$ is bounded by some function of $\text{pack}_H(G)$. Moreover,

it also follows that this bound does not hold any more if $H$ is non-planar (see also Diestel’s monograph [3, Corollary 12.4.10 and Exercise 40 of Chapter 12]). In [8] Fiorini, Joret, and Wood argued that the $O(k \cdot \log k)$ bound is the best we may expect when $H$ is a planar graph containing a cycle and they proved that if $H$ is acyclic, then $O(k \cdot \log k)$ can be reduced to $O(k)$. This implies that $O(k \cdot \log k)$ bound in Relation (1) is the best we may expect for non-acyclic planar graphs and the question remains whether the same bound can be achieved for every planar graph $H$. The most general result in this direction concerns the (parameterized) case where $H$ is the multi-graph containing two vertices and $r$ parallel edges between them. This graph is also known as the $r$-pumpkin and is denoted by $\theta_r$. In [7], Fiorini, Joret, and Sau proved that Relation (1) holds for every $H = \theta_r$, $r \geq 2$.

Another approach towards improving the bound in Relation (1) was to restrict the class of graphs where it applies. In this direction, it was proven by Fomin, Saurabh, and Thilikos in [9] that the log $k$ factor can be dropped in Relation (1), for all planar $H$‘s, in the case when we restrict $G$ to a graph class that excludes some fixed graph as a minor.

In this paper we provide a common extension of both the results of [7] and [9] that indicates how the effect of excluding a graph as a minor is reflected in the transition from $O(k \cdot \log k)$ to $O(k)$. Our result is the following:

**Theorem 1.** There exists a function $f : \mathbb{N} \to \mathbb{N}$ such that for every two positive integers $r, q$, and every graph $G$ excluding $K_q$ as a minor, it holds that $\text{cover}_{\theta_r}(G) \leq f(r) \cdot \text{pack}_{\theta_r}(G) \cdot \log q$.

Notice that if $\text{pack}_{\theta_r}(G) \leq k$ then $G$ does not contain a clique of $(k+1)(r+1)$ vertices as a minor. Therefore, if we set $q = (k+1)(r+1)$, we conclude that Relation (1) holds when $H = \theta_r$. This implies the main result of [7].

A consequence of the proof of Theorem 1 is the existence of a polynomial $O(\log OPT)$-approximation algorithm for both $\text{cover}_{\theta_r}$ and $\text{pack}_{\theta_r}(G)$. This improves the $O(\log n)$-approximation algorithm that was given by Joret, Paul, Sau, Saurabh, and Thomassé in [11] for the same parameters.

### 2 The proof

The proof of Theorem 1 is based on three results that we describe in this section.

Given a graph $G$, a *separation* of $G$ is a pair $(X_1, X_2)$ such that no edge of $G$ has an endpoint in $X_1 \setminus X_2$ and the other endpoint in $X_2 \setminus X_1$. The *order* of $(X_1, X_2)$ is the cardinality of the set $X_1 \cap X_2$.

We start with an observation in the case where there is no separation $(X_1, X_2)$ of $G$ for which both $G[X_1 \setminus X_2]$ and $G[X_2 \setminus X_1]$ contain some model of $H$ as a minor.

**Observation 1.** Let $H$ and $G$ be graphs and let $(X_1, X_2)$ be a separation of $G$ such that both $G_1 = G[X_1 \setminus X_2]$ and $G_2 = G[X_2 \setminus X_1]$ contain $H$ as a minor. Then

- $\text{cover}_H(G) \leq \text{cover}_H(G_1) + \text{cover}_H(G_2) + |X_1 \cap X_2|$
- $\text{pack}_H(G_1) + \text{pack}_H(G_2) \leq \text{pack}_H(G)$
- $\text{cover}_H(G_i) < \text{cover}_H(G)$, $i = 1, 2$.
- $\text{pack}_H(G_i) < \text{pack}_H(G)$, $i = 1, 2$. 

2
The following lemma reduces the problem to the case where for each separation \((X_1, X_2)\) of \(G\) of order at most \(2r - 2\), if \(G[X_1]\) does not contain a model of \(H\), then \(|X_1|\) is bounded by some function depending only on \(H\).

**Lemma 1.** For every \(q \in \mathbb{N}\) and graph \(H\) there exists a function \(f_H : \mathbb{N} \to \mathbb{N}\) such that for every \(K_q\)-minor free graph \(G\) there is a \(K_q\)-minor free graph \(G'\) such that

- \(\text{pack}_H(G) = \text{pack}_H(G')\)
- \(\text{cover}_H(G) = \text{cover}_H(G')\)
- for every separation \((X_1, X_2)\) of \(G'\), if \(G'[X_1 \setminus X_2]\) is a \(H\)-minor-free graph in \(G'\), then \(|X_1| \leq f_H(|X_1 \cap X_2|)\).

The proof of Lemma 1 is too long to fit in this extended abstract. It uses graph replacement techniques that have been developed in \([3]\) (see also \([1]\) and \([4]\)) that permit the replacement of the part of graph induced by \(X_1\) by another graph so that none of the parameters \(\text{pack}_H\) and \(\text{cover}_H\) change in the new graph.

We say that a graph \(G\) is \((\alpha, \beta)\)-loosely connected if for every separation \((X_1, X_2)\) of \(G\), \(|X_1 \cap X_2| \leq \alpha \Rightarrow \min\{|X_1|, |X_2|\} \leq \beta\).

Observation 1 and Lemma 1 applied for separators of order at most \(2r - 2\) reduce the proof of Theorem 1 to the case where \(G\) is \((2r - 2, f_H(2r - 2))\)-loosely connected. The second lemma derives from this assumption and is able to detect in such a graph a model of \(\theta_r\) that contains \(O(\log q)\) vertices.

**Lemma 2.** There is a function \(g : \mathbb{N} \to \mathbb{N}\) such that every \((2r - 2, f_H(2r - 2))\)-loosely connected \(K_q\)-minor free graph \(G\) contains a model of \(\theta_r\) with at most \(g(r) \cdot \log q\) vertices.

The proof of Lemma 2 is the core of our results and is technical. We enumerate below its main steps.

1. Take into account that every \(K_q\)-minor free graph has some vertex of degree < \(c \cdot q \cdot \sqrt{\log q}\) (see e.g., \([12,14]\)). Let \(d = f_H(2r - 2) \cdot \log((r - 1) \cdot c \cdot q \cdot \sqrt{\log q})\) and our target is to find a model of \(\theta_r\) in \(G\) with at most \(4 \cdot r \cdot d + 2\) vertices.
2. Let \(S = \{s_1, \ldots, s_l\}\) be a maximal 2d-scattered set (all its elements are in distance \(\geq 2d\) from each other) and consider a partition \(V_1, \ldots, V_l\) of \(V(G)\) such that
   - \(\forall i,j \forall u \in V_i \forall v \in V_j \text{ dist}_G(u, s_i) \leq \text{ dist}_G(u, s_j)\)
   - \(\forall i,j V_i \cap V_j = \emptyset\)
3. Let \(G_i^m = G[B_G^d(s_i)]\) and \(G_i = G[V_i]\). \((B_G^d(x))\) are the vertices that are in distance at most \(i\) from \(x\).
4. Let \(\mathcal{D}_i = \{\{X_j\} \subseteq V(U_i), U_i\}\) be an \(s_i\)-rooted tree-distance decomposition of \(G_i\) (for the definition of a rooted tree-distance decomposition, see \([13]\)).
5. Observe that \(\forall u, v \in V, \text{ dist}_G(u, v) \leq 2d\) and that all edges between \(G_i\) and \(G_j\) have endpoints from their \(d\)-th layer and then.
6. Prove that, unless we are done, all bags of \(\mathcal{D}_i\) have \(\leq r - 1\) vertices.
7. Prove that, unless we are done, in each \(G_{i,j} = G[V(G_i) \cup V(G_j)]\) there are at most \(r - 1\) paths from the \(d\)-th level of \(G_i\) to the \(d\)-th level of \(G_j\).
8. Deduce from the previous step and the \((2r - 2, f_H(2r - 2))\)-loose connectivity of \(G\) that there are at least \(2^{d/f_H(2r - 2)}\) pairwise vertex-disjoint paths between vertices in the \(d\)-th level of \(G_i\) and the union of the vertices of the \(d\)-th levels of all other \(G_j\)'s.
9. Deduce from the previous two steps that there is a collection of pairwise vertex-disjoint paths $\mathcal{P}$ in $G$, such that
   - if for some $i \neq j$ there is a path $P_{i,j} \in \mathcal{P}$ joining a vertex from $G_i$ with a vertex of $G_j$ then this is unique path in $\mathcal{P}$ with this property and
   - $G_i$ contains the endpoints of at least $\frac{\delta f_i}{f_e(2r-2)}$ paths from $\mathcal{P}$.

10. Contract all edges of every $G_i$, contract all but one edge of the paths in $\mathcal{P}$ and remove all other edges and isolated vertices. Let $H$ be the resulting minor of $G$. Prove that, from Step 8, $\delta(H) \geq \frac{\delta f_i}{f_e(2r-2)} = c \cdot q \cdot \sqrt{\log q}$, a contradiction to what we took into account in the 1st step.

We now require the following observation.

**Observation 2.** If $k = \text{pack}_{g_e}(G)$ and $W$ is the set of vertices of a model as in Lemma 2, then
   - $\text{pack}_{g_e}(G \setminus W) \leq \text{pack}_{g_e}(G) - 1 \leq k - 1$
   - $\text{cover}_{g_e}(G) \leq \text{cover}_{g_e}(G \setminus W) + |V(W)| \leq \text{cover}_{g_e}(G \setminus W) + g(r) \cdot \log q$.

It is now easy to verify that, taking into account Observation 2, Theorem 1 follows by successively applying Observation 1 and Lemmata 1 and 2.
