HAL is a multi-disciplinary open access archive for the deposit and dissemination of scientific research documents, whether they are published or not. The documents may come from teaching and research institutions in France or abroad, or from public or private research centers.

L’archive ouverte pluridisciplinaire HAL, est destinée au dépôt et à la diffusion de documents scientifiques de niveau recherche, publiés ou non, émanant des établissements d’enseignement et de recherche français ou étrangers, des laboratoires publics ou privés.
Design Of A Radiation Tolerant System For Total Ionizing Dose Monitoring Using Floating Gate And Radfet Dosimeters

R. FERRARO, S. DANZEC, M. BRUCOLI, A. MASI, M. BRUGGER and L. DILILLO

1. Abstract

The Total Ionizing Dose Monitor (TIDMon) is a radiation tolerant system designed to measure the effect of the TID on a new prototype of Floating Gate Dosimeter (FGDOS) and compare it against the Radiation-sensing Field Effect Transistors (RadFETs) dosimeter. In this work we present the design strategy adopted for the control of the sensors and the architecture, the radiation reliability and the performance achieved by the system.

2. Design Choices

Two parts compose the system:

- The tester part which is a generic radiation tolerant architecture able to acquire mixed-signals from the DUT and perform complex data processing.
- The DUTs part that contains the dosimeters sensors and the circuitry needed to manage them.

3. TID Monitoring procedure

The TIDMon measures every second the TID sensors and also the voltage regulators and the current source of the board in order to monitor the level of degradation of the tester.

4. Radiation Assurance

- A Triple Modular Redundancy (TMR) mitigation technique is applied on the FPGA IP core to register level manually.
- The board worked against radiation effects:
  - SEE and TID: > 230 MeV protons (up to 9.10^11 p/cm^2)
  - Displacement damage: 1 MeV neutrons (up to 4.10^12 n/cm^2)
  - TID: Co source up to 50 krad(Si) TID

5. Results

- In the nominal configuration of the FGDOS with a sampling of 3 Hz, the TIDMon is able to charge the sensors in less than 1 sample, thus the blind time is reduced to the minimum.
- The TIDMon can achieve a measure accuracy of 16 mrad(SI).
- The board worked without issues during the several test campaigns performed at CERN mixed-field facility or with ^60Co irradiation.

6. Conclusions

- The TIDMon allows us to finely characterize and find the best conditioning to use the FGDOS with the maximum performance as a TID sensor for CERN dosimetry purposes.
- The tester architecture proved to be robust against various harsh radioactive environments and can operate up to 30 krad(Si).
- The next step to consider for the Tester architecture will be to extend the lifetime of the FGDOS.
- The performances and the modularity of the test architecture provides us a quick and robust, ready-to-use test system able for other CERN radiation testing activities.
