This paper deals with the problem of obtaining stable and robust oscillations of underactuated mechanical systems. It is concerned with the Hopf bifurcation analysis of a Controlled Inertia Wheel Inverted Pendulum (C-IWIP). Firstly, the stabilization was achieved with a control law based on the Interconnection, Damping, Assignment Passive Based Control method (IDA-PBC). Interestingly, the considered closed loop system exhibits both supercritical and subcritical Hopf bifurcation for certain gains of the control law. Secondly, we used the center manifold theorem and the normal form technique to study the stability and instability of limit cycles emerging from the Hopf bifurcation. Finally, numerical simulations were conducted to validate the analytical results in order to prove that with IDA-PBC we can control not only the unstable equilibrium but also some trajectories such as limit cycles.

Keywords: Hopf-bifurcation, limit cycles, IDA-PBC control, normal form, center manifold.

1. Introduction

Different methodologies have been considered in the literature [Fradkov & Pogromsky, 1998] and [Leonard *et al.*, 1998] to stabilize oscillations for underactuated mechanical system [Choukchou-Braham *et al.*, 2014].

*khraiefnahla@gmail.com

Such trajectories have a practical importance, including its applications in mechanical engineering, acoustics, electronics, and biomechanics (perhaps even in finance and macroeconomics). One application deals with the Inertia Wheel Inverted Pendulum (IWIP). The system is composed of a symmetric disk (the inertia wheel), which is attached at the end of a pendulum body. The disk is free to rotate about an axis parallel to the axis of rotation of the pendulum. This system is controlled by a DC motor actuating the inertia wheel and the coupling torque generated by the angular acceleration of the wheel. Two control approaches dedicated to stable limit cycle generation for the IWIP were presented by Andary et al. The first [Andary *et al.*, 2009a] is based on partial nonlinear feedback linearization and dynamic control for optimal periodic reference trajectories tracking. The second [Andary *et al.*, 2012] is a dual Model-free controller tracking some parameterized reference trajectories. Effectiveness of the two controllers was illustrated through numerical and experimental results on the IWIP testbed. The adjustment of the frequency and amplitude of the obtained limit cycles presents the limitation of this work. Therefore, some optimization problems must be solved to obtain reference trajectories with different periods. Many studies [Fradkov & Pogromsky, 1998] , [Marsden & McCracken, 1976] dealt with useful self-oscillations emerging from Hopf bifurcation points.

Bifurcation analysis of the IWIP under control have been considered in the literature. Alonso et al. [Alonso *et al.*, 2005] used the bifurcation theory to classify different dynamical behaviors arising in the IWIP subject to bounded continuous state feedback control law. To limit the maximum amplitude of the control action, the control law is subject to a smooth saturation function, which was first introduced in [Alonso *et al.*, 2002] in order to stabilize the IWIP at the inverted position. The authors showed that the global dynamics of the IWIP change from a stable equilibrium point to a stable limit cycle via a Hopf bifurcation as certain control gains change. A similar work was realized on the Furuta pendulum by analyzing the Hopf bifurcation [Pagano *et al.*, 2000]. Recently, Nikolov and Nedev [Nikolov & Nedev, 2016] analyzed bifurcation and dynamic behavior of the IWIP with bounded control by means of the theory of Poincaré-Andronov-Hopf (PAH).

In this study we investigated the stabilization of oscillations by a passivity-based design control, namely Interconnection and Damping assignment Passivity Based Control (IDA-PBC) introduced first in [Ortega *et al.*, 2002] and revisited in [Khraief-Haddad *et al.*, 2014] and [Khraief-Haddad *et al.*, 2015]. The main contribution of the present work involves the tracking of reference trajectories (various stable limit cycles) from stabilization of the IWIP around equilibrium point by IDA-PBC controller. The IWIP transformed via IDA-PBC control into a generalized Hamiltonian closed-loop system exhibits critical Hopf bifurcation points. Stable and unstable limit cycles emerge at these bifurcations. To study the direction and stability of such periodic solutions we proceeded to compute the first Lyapunov coefficient at the Hopf bifurcation. Practically, such solutions coincide with a great variety of vibrations (useful or destructive). At first, we analyzed the stability of the equilibrium point with respect to the control gains. Moreover, we developed conditions for the existence of the Hopf bifurcation and then of periodic oscillations. Furthermore, stability of these periodic oscillations were investigated analytically by means of the first Lyapunov value as a function of some IDA-PBC control gains. The paper is organized as follows. In section 2 a brief description of the inertia wheel inverted pendulum and IDA-PBC controller is given. Section 3 deals with the Hopf-bifurcation analysis of the C-IWIP. The dynamical behaviour of the C-IWIP when Hopf bifurcation occurs is described in section 4. Analytical results about direction and stability of critical Hopf bifurcation points are given in section 5. Section 6 is dedicated to simulation results. Finally, concluding remarks are drawn in Section 7.

2. Controlled Inertia Wheel Inverted Pendulum (C-IWIP)

2.1. *The inertia wheel inverted pendulum (IWIP)*

2.1.1. *Description*

The underactuated system called IWIP, studied in this paper, is illustrated in figure(1). It has two degrees of freedom, the active one is the rotating disc and the passive joint is the pendulum. The generated torque produces an angular acceleration of the end mass which induces a coupling torque at the axis of

the pendulum. The parameters of the system are summarized in (Table 1.).

Figure 1. Inertia Wheel Inverted Pendulum.

Table 1.

Description of dynamical parameters of the IWIP

Description	Notation	Units
Pendulum angle with respect to vertical axis	θ_1	rad
Wheel angle with respect to pendulum axis	θ_2	rad
Mass of pendulum	m	kg
Mass of the Wheel	M	kg
Length from pendulum base (PB) to pendulum center of mass (PC)	l	m
Length from pendulum base (PB) to Wheel center of mass (WC)	L	m
Rotational Inertia of pendulum about pendulum center of mass (PC)	I_{PC}	kg.m ²
Rotational Inertia of pendulum about pendulum base (PB)	I_{PB}	kg.m ²
Rotational Inertia of Wheel about Wheel center of mass (WC)	I_{WC}	m ²
Constant of gravitational acceleration	g	m/s ²

2.1.2. IWIP modelling

55 The Euler-Lagrange equations of motion can be written as [Spong & Vidyasagar, 1989]:

$$\begin{pmatrix} (a + I_{WC}) & I_{WC} \\ I_{WC} & I_{WC} \end{pmatrix} \begin{pmatrix} \ddot{\theta}_1 \\ \ddot{\theta}_2 \end{pmatrix} - \begin{pmatrix} b_1 g \sin \theta_1 \\ 0 \end{pmatrix} = \begin{pmatrix} 0 \\ u \end{pmatrix} \quad (1)$$

where : $\theta = [\theta_1 \ \theta_2]^T$, u is the torque applied by the motor to spin the wheel and :

$$\begin{aligned} a &= ML^2 + I_{PB} \\ b_1 &= ml + ML. \end{aligned} \quad (2)$$

Let us introduce the following change of coordinates:

$$\begin{bmatrix} q_1 \\ q_2 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} \theta_1 \\ \theta_2 \end{bmatrix} \quad (3)$$

This leads to a simplified model:

$$\begin{bmatrix} a & 0 \\ 0 & I_{WC} \end{bmatrix} \begin{bmatrix} \ddot{q}_1 \\ \ddot{q}_2 \end{bmatrix} - \begin{bmatrix} b_1 g \sin q_1 \\ 0 \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix} u. \quad (4)$$

The model (4) can be written through Hamilton's equations of motion as [Santibañez *et al.*, 2005] [Palacios, 2006]:

$$\begin{bmatrix} \dot{q}_1 \\ \dot{q}_2 \\ \dot{p}_1 \\ \dot{p}_2 \end{bmatrix} = \begin{bmatrix} \frac{p_1}{a} \\ \frac{p_2}{I_{WC}} \\ b_1 g \sin q_1 - u \\ u \end{bmatrix} \quad (5)$$

Where $q = [q_1 \ q_2]^T$ and $p = [p_1 \ p_2]^T = [a\dot{q}_1 \ I_{WC}\dot{q}_2]^T$ are the generalized positions and momenta, respectively. Which leads to write the Hamiltonian function as:

$$H(q, p) = \frac{1}{2} p^T M^{-1}(q) p = \frac{1}{2} \left[\frac{p_1^2}{a} + \frac{p_2^2}{I_{WC}} \right] \quad (6)$$

2.2. Design of the control law for the IWIP

2.2.1. IDA-PBC controller

The control problem is to stabilize the pendulum at the upward position with the inertia disc aligned. We proposed to revisit the IDA-PBC control [Ortega *et al.*, 2002]. The designed controller is formulated for port-controlled hamiltonian (PCH) models. IDA-PBC aims to find a state feedback control u such that the closed-loop dynamics is a port-hamiltonian system of the form:

$$\dot{x} = [J_d(x, u) - R_d(x)] \frac{\partial H_d}{\partial x}(x) \quad (7)$$

Where the new energy function H_d has a local minimum at the desired equilibrium point. For the IWIP the desired hamiltonian function can be defined as:

$$H_d(q, p) = \frac{1}{2} p^T M_d^{-1}(q) p + V_d(q) \quad (8)$$

where $M_d = \begin{pmatrix} a_1 & a_2 \\ a_2 & a_3 \end{pmatrix}$ with $a_1 > 0$, $a_1 a_3 > a_2^2$ and $a_1 + a_2 < 0$.

In [Ortega *et al.*, 2002] the authors propose the following control law for the IWIP:

$$u = \gamma_1 \sin(q_1) + k_p(q_2 + \gamma_2 q_1) + k_v k_2(\dot{q}_2 + \gamma_2 \dot{q}_1) \quad (9)$$

where

$$\gamma_1 > b_1 g$$

$$\gamma_2 = - \frac{a \gamma_1}{I_{WC}(\gamma_1 - b_1)}$$

$$k_2 > 0$$

Together with k_p and k_v positive arbitrary constants, define the tuning gains.

The control law (9) can be rewritten [Khraief-Haddad *et al.*, 2014] and [Khraief-Haddad *et al.*, 2015] in terms of the generalized coordinates q and momenta p as

$$u = \underbrace{\gamma_1 \sin(q_1) + k_1 q_1 + k_2 q_2}_{u_{es}} + \underbrace{k_3 p_1 + k_4 p_2}_{u_{di}} \quad (10)$$

where u_{es} is the energy shaping control to assign the equilibrium and u_{di} injects damping to achieve asymptotic stability.

$$k_1 = k_p \gamma_2$$

$$k_2 = k_p$$

$$k_3 = k_v \left(\frac{a_2 + a_3}{a_1 a_3 - a_2^2} \right)$$

$$k_4 = -k_v \left(\frac{a_1 + a_2}{a_1 a_3 - a_2^2} \right)$$

2.2.2. Simulation results

Table 2.
Dynamic Parameters of the IWIP

Parameter	Description	Value	Unit
m	pendulum mass	3.228	Kg
M	mass of the wheel	0.33081	Kg
l	Pendulum center of mass position	0.06	m
L	Wheel center of mass position	0.044	m
I_1	Pendulum inertia	0.0314	Kgm^2
I_2	Wheel inertia	$4.176e^{-4}$	Kgm^2

In the simulations below we considered the PCH model(5). IWIP parameters are described in table 2. They were identified on the real prototype of the system [Andary *et al.*, 2009b], which was designed and developed at LIRMM ¹. Here after, we will present and discuss simulation results obtained on the IWIP when applying IDA-PBC control law (10). We chose the initial configuration $[q_1 \ q_2 \ p_1 \ p_2]^T = (0.2 \ 0 \ 0 \ 0)^T$. The remaining control parameters were selected as $\gamma_1 = 6.1284$, $k_1 = 1.0367$ and $k_2 = 0.0011$. $k_3 = 16.62$ and $k_4 = 3.4640$.

Figure(2) depicts joint positions and velocities and also displays the control input. The performance of the IDA-PBC controller was observed by the convergence towards the equilibrium point $(0, 0, 0, 0)^T$.

3. Hopf Bifurcation analysis of the C-IWIP

3.1. Equilibrium point

The equilibrium point of the closed loop system (5) is determined when $\dot{q}_1 = 0$, $\dot{q}_2 = 0$, $\dot{p}_1 = 0$, $\dot{p}_2 = 0$ and thus:

$$\begin{cases} p_1 = 0 \\ p_2 = 0 \\ \sin q_1 = 0 \\ k_1 q_1 + k_2 q_2 = 0 \end{cases} \quad (11)$$

Therefore, the equilibrium point of the system (5) is given by:

$$\mathbf{x}_{eq} = \begin{bmatrix} k\pi \\ -k\pi \frac{k_1}{k_2} \\ 0 \\ 0 \end{bmatrix} \quad (12)$$

So we can distinguish $x_{eq} = (2k\pi, -2k\pi \frac{k_1}{k_2}, 0, 0)$ (inverted or upward position) or $x_{eq} = ((2k+1)\pi, -(2k+1)\pi \frac{k_1}{k_2}, 0, 0)$ (hanging or rest position), $k \in \mathbb{Z}$. To avoid considering an infinite number of equilibria, we dealt only with one equilibrium point $x_{eq} = (0, 0, 0, 0)^T$ stabilized by the IDA-PBC control and corresponding to the pendulum at the inverted position with zero disc velocity.

3.2. Existence of the Hopf Bifurcation

Let $X = (q, p)^T$, and $p = (k_1, k_2, k_3, k_4)^T$. Recall (5) which we restate here:

$$\dot{X} = F(X, p), \quad X \in \mathbb{R}^4, \quad p \in \mathbb{R}^4 \quad (13)$$

Equation (13) represents the vector field of the C-IWIP.

3.2.1. Jacobian Matrix

The Jacobian matrix \mathcal{J} around the equilibrium point \mathbf{x}_{eq} of the closed-loop system (5) is defined as follows:

$$\mathcal{J} = \begin{bmatrix} 0 & 0 & \frac{1}{a} & 0 \\ 0 & 0 & 0 & \frac{1}{I_{wc}} \\ b_1 g - \gamma_1 - k_1 & -k_2 & -k_3 & -k_4 \\ \gamma_1 + k_1 & k_2 & k_3 & k_4 \end{bmatrix} \quad (14)$$

Let us make a variable change as: $a = \frac{1}{a}$, $c = \frac{1}{I_{wc}}$, $b = b_1 g$ and $\gamma = \gamma_1$. Then, we obtain:

$$\mathcal{J} = \begin{bmatrix} 0 & 0 & a & 0 \\ 0 & 0 & 0 & c \\ b - \gamma - k_1 & -k_2 & -k_3 & -k_4 \\ \gamma + k_1 & k_2 & k_3 & k_4 \end{bmatrix} \quad (15)$$

3.2.2. Eigenvalues of the Jacobian Matrix

The eigenvalues of the Jacobian matrix \mathcal{J} (15) are computed by solving the following equation

$$\det(\lambda(p)\mathcal{I} - \mathcal{J}) = 0 \quad (16)$$

It is easy to demonstrate that relation (16) can be reformulated as follows:

$$\lambda(p)^4 + (k_3 - k_4) \lambda(p)^3 + (a(\gamma - b + k_1) - ck_2) \lambda(p)^2 + abk_4 \lambda(p) + abck_2 = 0 \quad (17)$$

We assume that the Jacobian matrix \mathcal{J} admits two complex-conjugate eigenvalues, $\alpha(p) \pm i\beta(p)$ where $\beta(p) > 0$, and two eigenvalues μ and η verifying $(\mu + \eta) < 0$ and $(\mu\eta) > 0$ and are both real. Thus, the characteristic polynomial can be expressed as

$$(\lambda(p) - \mu) (\lambda(p) - \eta) (\lambda(p) - (\alpha(p) + i\beta(p))) (\lambda(p) - (\alpha(p) - i\beta(p))) = 0 \quad (18)$$

This last relation can be cast as:

$$\lambda(p)^4 + [-2\alpha(p) - (\mu + \eta)] \lambda(p)^3 + [(\alpha(p)^2 + \beta(p)^2) + 2\alpha(p)(\mu + \eta) + \mu\eta] \lambda(p)^2 + [-(\mu + \eta)(\alpha(p)^2 + \beta(p)^2) - 2\alpha(p)\mu\eta] \lambda(p) + \mu\eta(\alpha(p)^2 + \beta(p)^2) = 0 \quad (19)$$

According to expressions (17) and (19) we can write ²:

$$-2\alpha - (\mu + \eta) = k_3 - k_4 \quad (20a)$$

$$(\alpha^2 + \beta^2) + 2\alpha(\mu + \eta) + \mu\eta = a(\gamma - b + k_1) - ck_2 \quad (20b)$$

$$-(\mu + \eta)(\alpha^2 + \beta^2) - 2\alpha\mu\eta = abk_4 \quad (20c)$$

$$\mu\eta(\alpha^2 + \beta^2) = abck_2 \quad (20d)$$

3.2.3. The Hopf bifurcation

The Hopf bifurcation occurs if and only if $\alpha(p) = 0$ and $\beta(p) \neq 0$. Then, relations in (20) can be simplified as follows:

$$\mu + \eta = k_4 - k_3 \quad (21a)$$

$$\beta^2 + \mu\eta = a(\gamma - b + k_1) - ck_2 \quad (21b)$$

$$-(\mu + \eta)\beta^2 = abk_4 \quad (21c)$$

$$\mu\eta\beta^2 = abck_2 \quad (21d)$$

The problem was then to find the gain parameters, k_i , for which the Hopf bifurcation happens. The functions in (21) can be reformulated as

$$\mu + \eta = k_4 - k_3 \quad (22a)$$

$$\beta^4 - (a(\gamma - b + k_1) - ck_2)\beta^2 + abck_2 = 0 \quad (22b)$$

²In the following we take $\beta(p) = \beta$

$$k_4 = \frac{\beta^2}{ab + \beta^2} k_3 \quad (22c)$$

$$\mu\eta = \frac{abc}{\beta^2} k_2 \quad (22d)$$

Using relation (22c) in (22a) and relying on expression (22d), we emphasize that: $\mu + \eta < 0$ and $\mu\eta > 0$.

125 Furthermore, relying on the previous relations in (22), it is worth noting that β is the solution of (22b) and it depends only on the two parameters k_1 and k_2 . Moreover, k_4 is proportional to k_3 and it depends on β . Then, by choosing the value of k_1 , k_2 and k_3 , we can calculate the value of the k_4 at which the Hopf bifurcation occurs. We state that the gain k_3 does not affect the occurrence of the HB.

By solving relation (22b), it is easy to show that there are two solutions β_1 and β_2 defined as follows:

$$\beta_1 = \sqrt{\frac{a(\gamma - b + k_1) - ck_2 - \sqrt{(a(\gamma - b + k_1) - ck_2)^2 - 4abck_2}}{2}} \quad (23a)$$

$$\beta_2 = \sqrt{\frac{a(\gamma - b + k_1) - ck_2 + \sqrt{(a(\gamma - b + k_1) - ck_2)^2 - 4abck_2}}{2}} \quad (23b)$$

130 In (23), we have $\beta_1 < \beta_2$. In fact, both solutions, β_1 and β_2 , exist if and only if the following three conditions are met:

$$(a(\gamma - b + k_1) - ck_2)^2 - 4abck_2 > 0 \quad (24a)$$

$$a(\gamma - b + k_1) - ck_2 - \sqrt{(a(\gamma - b + k_1) - ck_2)^2 - 4abck_2} > 0 \quad (24b)$$

$$a(\gamma - b + k_1) - ck_2 + \sqrt{(a(\gamma - b + k_1) - ck_2)^2 - 4abck_2} > 0 \quad (24c)$$

135 **Proposition 3.1.** Consider the C-IWIP represented by the vector field (13). According to conditions (24b) and (24c) and as $k_1 > 0$ and $k_2 > 0$, it follows that: $a(\gamma - b + k_1) - ck_2 > 0$. Hence, relying on (24a), it is easy to show that, for some $k_2 > 0$, we have:

$$k_1 > b - \gamma + \frac{c}{a}k_2 + 2\sqrt{\frac{bc}{a}}\sqrt{k_2} \quad (25)$$

140 Expression (25) represents the condition on k_1 with respect to k_2 for the existence of the Hopf bifurcation for the C-IWIP.

4. Dynamical behaviour of the C-IWIP when Hopf bifurcation occurs

In this section we are interested in analyzing the dynamical behaviour of the C-IWIP near the equilibrium point x_{eq} when the controlled parameters represented by p are varied.

145 Fig. 3 illustrates such conditions in the parameters space (k_1, k_2) . HB denotes the zone in which the two Hopf bifurcations (HB) occur. In the white space, the two HB disappear simultaneously. This type of

curve is known as the failure of the transversality condition of the eigenvalue crossing of the regular Hopf bifurcation. The BC-HB represents a degenerate Hopf bifurcation and is defined by the following equation

$$k_{1,c} = b - \gamma + \frac{c}{a}k_2 + 2\sqrt{\frac{bc}{a}}\sqrt{k_2} \quad (26)$$

Figure 3. Existence of the Hopf Bifurcation (HB) in the parameters space (k_1, k_2) .

Hence, for such expression (26), we obtain: $\beta_1 = \beta_2 = \beta_c$

$$\beta_c = \sqrt{\sqrt{abc}\sqrt{k_2}} \quad (27)$$

Then, the two Hopf bifurcations enter in collision and are replaced by only one Hopf bifurcation. Accordingly, The BC-HB reveals the curve for which only one Hopf exists. Varying one parameter k_1 or k_2 or the two parameters together provokes the disappearance of these two HBs and the birth of only one HB. Thus, slightly varying these two parameters, the HB disappears and thus HB no longer exists.

Fig. 4 shows the variation of β_1 and β_2 in (23) as the gain k_1 varies. Here, we chose 5 different fixed values of the gain k_2 : $k_2 = 0.001$, $k_2 = 0.02$, $k_2 = 0.05$, $k_2 = 0.1$ and $k_2 = 0.15$. Small circles show the critical value at which only one HB occurs. The value of β is given by expression (27). It is obvious that for some fixed value of k_2 , and as k_1 decreases, the two HBs meet and annihilate with each other at the critical value $k_{1,c}$ given via relation (26). Hence by slightly decreasing k_1 , the HB disappears suddenly. Relying on Fig. 4, for $k_2 = 0.001$ and as $k_1 > 0$, the two HBs always coexist.

We dealt with the variation of the gain k_4 as k_1 varied for a constant value of k_3 and for different values of k_2 . Such investigation was realized by means of relation (22c). Let $k_3 = 38.4$. Fig. 5 shows the variation of k_4 with respect to k_1 for some values of k_2 .

For example, for $k_1 = k_p * \gamma_2 = 1.036691874482759$, $k_2 = k_p = 0.0011$ and $k_3 = 38.4$, the two values of k_4 were calculated to be about: $k_{4,1} = 0.871599173381224$ and $k_{4,2} = 27.197725293683821$.

5. Direction and stability of the Hopf bifurcation

5.1. Analytical analysis

In the previous section, we obtained some conditions which guarantee that the C-IWIP undergoes Hopf bifurcation at the equilibrium point x_{eq} . In this section we will use the normal form and the center manifold theory [Kuznetsov, 1998], [Wiggins, 2003] and [Guckenheimer & Holmes, 1983] to give the explicit formulae

Figure 4. Variation of β_1 and β_2 with respect to parameter k_1 for fixed values of k_2 .

Figure 5. Variation of k_4 with respect to parameter k_1 , for $k_3 = 38.4$ and for fixed values of k_2 : $k_2 = 0.001$, $k_2 = 0.02$, $k_2 = 0.05$, $k_2 = 0.1$ and $k_2 = 0.15$.

which determine the direction and stability of the periodic solutions bifurcating from equilibrium point x_{eq} at some critical values of the controlled parameters denoted by vector p . In what follows we will assume that we are dealing with a single scalar parameter, i.e $p = k_2$. We fix $k_1 = k_{1,c}$ and leave k_2 free to vary. In this case $\beta^2 = \beta_c^2 = \sqrt{abck_2}$, so we deal only with one Hopf bifurcation. According to expressions (21), (22), (26) and (27) we write the following expressions:

$$k_1 = b - \gamma + \frac{\beta^4}{a^2b} + 2\frac{\beta^2}{a} \quad (28a)$$

$$k_2 = \frac{\beta^4}{abc} \quad (28b)$$

$$k_3 = -(\mu + \eta)\left(1 + \frac{\beta^2}{ab}\right) \quad (28c)$$

$$k_4 = -(\mu + \eta)\left(\frac{\beta^2}{ab}\right) \quad (28d)$$

The jacobian matrix(15) evaluated at x_{eq} can be rewritten as follows:

$$\mathcal{J} = \begin{bmatrix} 0 & 0 & a & 0 \\ 0 & 0 & 0 & c \\ -\frac{\beta^4}{a^2b} - 2\frac{\beta^2}{a} & -\frac{\beta^4}{abc} & (\mu + \eta)\left(1 + \frac{\beta^2}{ab}\right) & (\mu + \eta)\left(\frac{\beta^2}{ab}\right) \\ b + \frac{\beta^4}{a^2b} + 2\frac{\beta^2}{a} & \frac{\beta^4}{abc} & -(\mu + \eta)\left(1 + \frac{\beta^2}{ab}\right) & -(\mu + \eta)\left(\frac{\beta^2}{ab}\right) \end{bmatrix} \quad (29)$$

Whether Hopf bifurcation is subcritical or supercritical, it is determined by the sign of the first Lyapunov coefficient $l_1(0)$ of the C-IWIP near the equilibrium point. In what follows, we will adopt the convention of Kuznetsov [Kuznetsov, 1998] and [Kuehn, 2010] to compute $l_1(0)$.

Suppose the system (13) is written as:

$$\dot{X} = \mathcal{J}X + f(X) \quad (30)$$

Where $f(X) = O(\|X^2\|)$ is a smooth function. Write the Taylor expansion to transform (30) into the following normal form:

$$\dot{X} = \mathcal{J}X + \frac{1}{2}B(X, X) + \frac{1}{6}C(X, X, X) + O(\|X^4\|) \quad (31)$$

Where $B(u, v)$ and $C(u, v, w)$ are multilinear functions with the following components:

$$B_i(u, v) = \sum_{j,k=1}^4 \frac{\partial^2 f_i(\xi)}{\partial \xi_j \partial \xi_k} \Big|_{\xi=0} u_j v_k$$

$$C_i(u, v, w) = \sum_{j,k,l=1}^4 \frac{\partial^3 f_i(\xi)}{\partial \xi_j \partial \xi_k \partial \xi_l} \Big|_{\xi=0} u_j v_k w_l$$

We can check easily that for the C-IWIP equation (30) is given by:

$$\dot{X} = \begin{bmatrix} 0 & 0 & a & 0 \\ 0 & 0 & 0 & c \\ b - \gamma - k_1 & -k_2 & -k_3 & -k_4 \\ \gamma + k_1 & k_2 & k_3 & k_4 \end{bmatrix} X + \begin{bmatrix} 0 \\ 0 \\ (b - \gamma)\frac{q_1^3}{6} \\ -\gamma\frac{q_1^3}{6} \end{bmatrix} + O(\|X^4\|) \quad (33)$$

We can verify also that the bilinear function $B(u, v) = 0$ while the multilinear function $C(u, v, w)$ can be expressed as :

$$C(u, v, w) = \begin{bmatrix} 0 \\ 0 \\ (b - \gamma)u_1 v_1 w_1 \\ -\gamma u_1 v_1 w_1 \end{bmatrix} \quad (34)$$

The matrix \mathcal{J} has eigenvalues : $\lambda_{1,2} = \pm i\beta$ for $\beta > 0$, $\lambda_3 = \mu$ and $\lambda_4 = \eta$. Let $q \in \mathbb{C}^4$ be the eigenvector of λ_1 and $p \in \mathbb{C}^4$ the corresponding eigenvector of the transpose \mathcal{J}^T i.e:

$\mathcal{J}q = i\beta q$; $\mathcal{J}\bar{q} = -i\beta\bar{q}$ and $\mathcal{J}^T p = -i\beta p$; $\mathcal{J}^T \bar{p} = i\beta\bar{p}$. It is easy to check (with mupad/Matlab) that the

vectors :

$$q = \begin{pmatrix} \frac{a\beta i}{ab + \beta^2} \\ -\frac{ci}{ab + \beta^2} \\ \frac{\beta}{ab + \beta^2} \\ 1 \end{pmatrix} \quad (35a)$$

$$p = \begin{pmatrix} -\frac{(\beta^2+ab)(\beta^3+ab\beta-ab\eta i-ab\mu i)}{2a^2b\beta(\mu+\eta)} \\ -\frac{\beta^4+ab\beta^2}{2abc(\mu+\eta)} \\ -\frac{(\beta^2+ab)(abi-\mu\beta-nu\beta+\beta^2i)}{2ab\beta(\mu+\eta)} \\ \frac{(\beta^2+ab)(\mu+\eta-\beta i)}{2ab(\mu+\eta)} \end{pmatrix} \quad (35b)$$

are eigenvectors of \mathcal{J} and \mathcal{J}^T corresponding to respectively the eigenvalues $i\beta$ and $-i\beta$. Note that the p is normalized so that the standard complex inner product with q satisfies: $\bar{p}^T q = \sum_{j=1}^4 \bar{p}_j^T q_j = 1$. The first Lyapunov coefficient of the Hopf bifurcation is defined by [Kuznetsov, 1998]:

$$l_1(0) = \frac{1}{2\beta} (\bar{p}^T C(q, q, \bar{q}) - 2\bar{p}^T B(q, \mathcal{J}^{-1} B(q, \bar{q})) + \bar{p}^T B(\bar{q}, (2i\beta I_4 - \mathcal{J})^{-1} B(q, q))) \quad (36)$$

195 Using expressions of q, p in (35) and $C(u, v, w)$ in (34) and relying on (36) we obtained the first Lyapunov coefficient of the C-IWIP for the considered Hopf bifurcation point as follows:

$$l_1(0) = \frac{1}{2\beta} \text{Re}[\bar{p}^T C(q, q, \bar{q})] \quad (37a)$$

$$l_1(0) = \frac{130.7340692 \beta (\beta^2 - 93.42868368)}{(\mu + \eta) (\beta^2 + 46.71434184)^2} \quad (37b)$$

We set $\varsigma = 93.42868368$.

200 **Proposition 5.1.** *Consider the C-IWIP represented by the vector field (13). According to the expression of the first Lyapunov coefficient (37b) the Hopf bifurcation (in the case where $\beta = \beta_c$) is non degenerate and supercritical if and only if $\beta^2 > \varsigma$.*

We can now return to the IDA-PBC control parameters by making some substitutions and met the following result:

205 **Proposition 5.2.** *For all initial conditions -except a set of zero measures- the IDA-PBC drives the IWIP towards a stable limit cycle with the period $\frac{2\pi}{\beta}$ if control parameters satisfy the following conditions:*

$$k_1 > b - \gamma + \frac{\varsigma^2}{a^2b} + 2\frac{\varsigma^2}{a} \quad (38a)$$

$$k_2 > \frac{\varsigma^2}{abc} \quad (38b)$$

$$\frac{k_4}{k_3} > \frac{\varsigma}{\varsigma + ab} \quad (38c)$$

5.2. IDA-PBC controller gains and IWIP stable oscillations

210 In this section, we will perform some graphical illustrations of the boundary stability with respect to IDA-PBC controller gains. The control objective was to obtain stable and robust oscillations for the IWIP. Thus, the region defined by (38) with respect to the first Lyapunov coefficient is depicted in (6). Here we note that we did simulations when we take into account the assumption $\mu + \nu < 0$. It is seen that Hopf bifurcation is supercritical when $l_1(0) \leq 0$ or $\beta > \sqrt{\varsigma} = 9.66$.

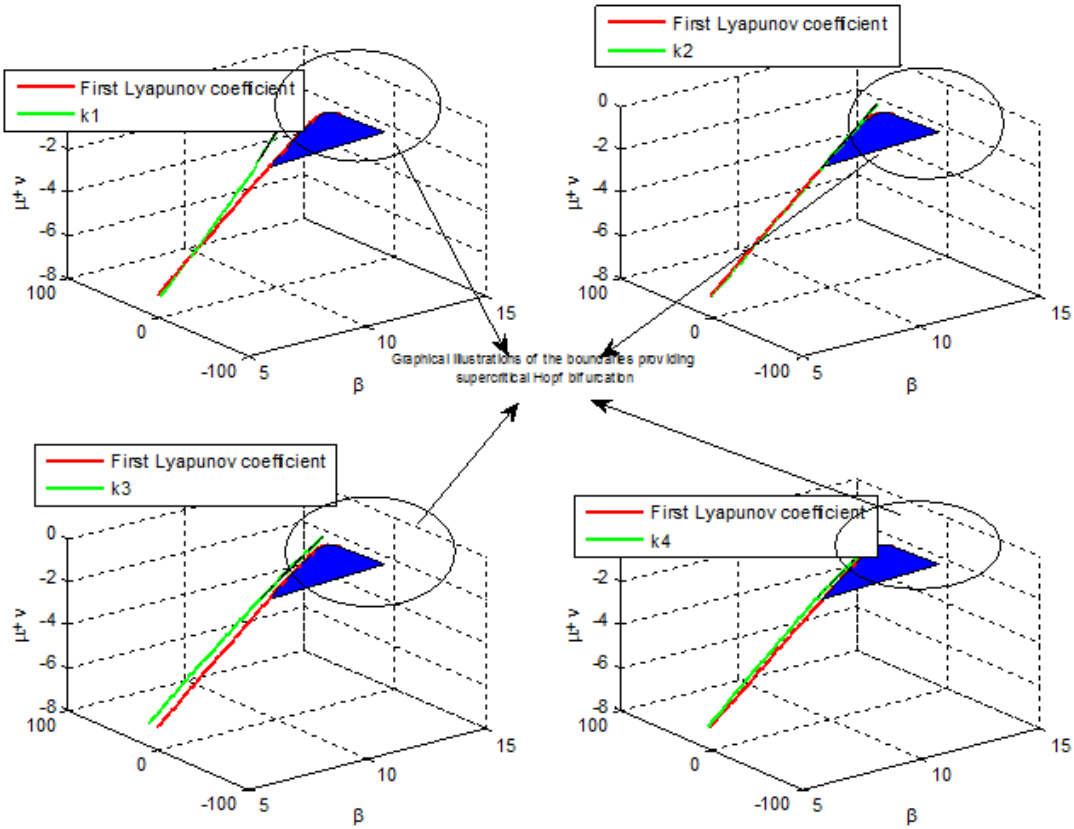

Figure 6. Graphical illustration of supercritical Hopf bifurcation zones with respect to parameters k_1 , k_2 , k_3 and k_4

6. Numerical Simulation

215 Some numerical Hopf bifurcation analyses of the C-IWIP were carried out to attest the effectiveness of the analytical results obtained in the previous section. We performed a numerical computation of Hopf bifurcation points and the first Lyapunov coefficient $l_1(0)$, using the well-known MATCONT package [Dhooge *et al.*, 2003] which used the AUTO package to the numerical continuation of limit cycles and the stability index.

220

6.1. Hopf bifurcation detection for the C-IWIP

This study dealt with one-parameter bifurcation analysis of equilibria, thus we fixed three parameters and varied only one. For example for $k_2 = 0.0782$, $k_3 = 4.94$ and $k_4 = 3.4640$ we found only one critical value of $k_{1,1}^c = 12.386476$ at which the Hopf bifurcation occurred (see figure(7)). Moreover, we had $\mu = -0.738041 + i8.90205$, $\eta = -0.738041 - i8.90205$, $l_1(0) = -64.76669e-2$ and $\beta = 10.4705$. We proved that the previous results coincide with conditions met in proposition 5.1 and 5.2. Then we choose k_2 , k_3 and k_4 satisfying conditions (38). Here, we took $k_2 = 0.0783$ and fixed $k_3 = 38.4$ and $k_4 = 35.97$. By varying the parameter k_1 we found one critical value of $k_{1,2}^c = 34.905957$ at which the Hopf bifurcation occurred (see figure (8)). Tables 3. and 4. show a comparison between numerical and analytical results for both critical points ($k_{1,1}^c$ and $k_{1,2}^c$). It can be shown that both results coincide. Moreover, all values attain assumptions met in subsection 5.1. The difference between each cycle is the amplitude and the frequency. Relying on proposition 5.1 the period of the stable limit cycles around the critical parameters $k_{1,1}^c$ and $k_{1,2}^c$ were respectively : $T_{1,1}^c = 0.6s$ and $T_{1,2}^c = 0.2389s$.

6.2. Stable Limit Cycle generation of the IWIP via IDA-PBC

Simulation results are presented and discussed in what follows. They attest the effectiveness of the designed IDA-PBC control (10) for the tracking of period-1 stable limit cycle emerging from supercritical Hopf bifurcation. Simulation results were obtained using Matlab software. Our objective was to investigate the influence of the designed control law with the critical gains $k_{1,1}^c$ and $k_{1,2}^c$ on the dynamic behavior of the controlled IWIP and then on the convergence towards period-1 stable limit cycle. It is worth mentioning that parameter description and the choice of initial value of X was motivated by the physical properties of the inverted pendulum, as the pendulum angle value is 10° at a standstill. Table 5. gives the description and the numerical values of all the needed parameters. The following simulations deal with two cases:

Table 5.

Description and Numerical values for critical points

Parameter	Description	$k_{1,1}^c$	$k_{1,2}^c$
$l_1(0)$	The first Lyapunov coefficient	-0.6147	-1.5526
X_0	Initial value	[0.2; 0; 0; 0]	[0.2; 0; 0; 0]
k_1	Control parameter 1	12.386476	34.905957
k_2	Control parameter 2	0.0782	0.0783
k_3	Control parameter 3	4.94	38.4
k_4	Control parameter 4	3.4640	35.972012

6.2.1. Case 1 : $k_1 = k_{1,1}^c$

In this first case, uncertainties and external disturbances were neglected. The proposed simulation is started from the initial condition given in Table 5. Then the application of the control law (10) to the nominal nonlinear dynamics of the IWIP gave results shown in figures (9) and (10). The former displays the pendulum joint position and velocity versus time. These results clearly show the convergence of the trajectory of the controlled IWIP to the desired stable period-1 limit cycle. It can be observed from the displayed results that the period of the reference limit cycle is about 0.6207[s]. The latter represents the control law and the phase portrait showing clearly the convergence from the initial condition to a stable limit cycle.

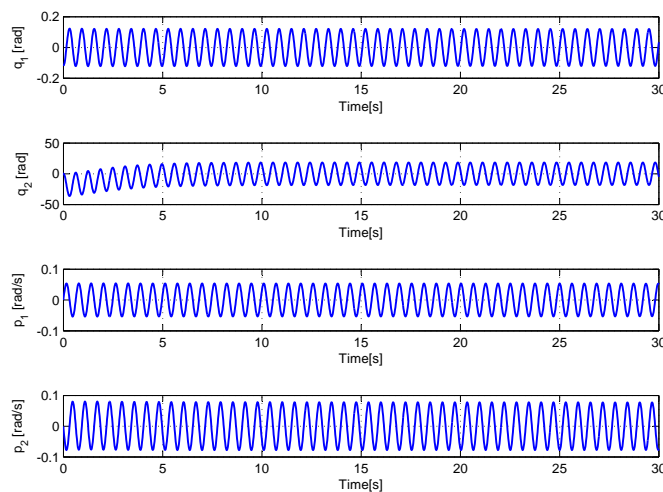

Figure 9. Pendulum joint position and velocity versus time (Initial conditions are [0.2; 0; 0; 0])

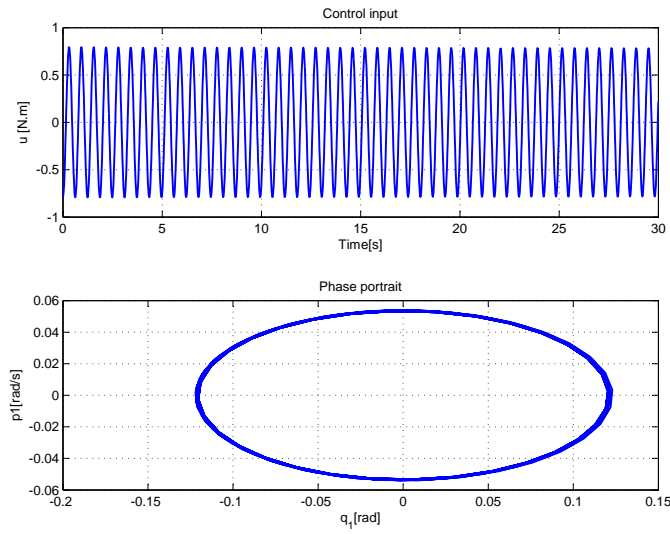

Figure 10. Phase portrait when $k_1 = k_{1,1}^c$

6.2.2. Case 2 : $k_1 = k_{1,2}^c$

255

Similarly uncertainties and external disturbances were neglected in this case. The proposed simulation started from the initial condition given in Table 5. Then, application of the control law (10) to the nominal nonlinear dynamics of the IWIP gave results depicted in figures (11) and (12). The former displays the pendulum joint position and velocity versus time. These results clearly show the convergence of the trajectory of the controlled IWIP to the desired stable period-1 limit cycle. It can be observed from the displayed results that the period of the reference limit cycle is about 0.2388[s]. The latter represents the control law and the phase portrait showing clearly the convergence from the initial condition to a stable limit cycle.

7. Conclusion and future works

In this work we studied the dynamical behaviour of a conventional inertia wheel inverted pendulum with a disk in its free extreme. The system is underactuated since the pendulum can rotate freely around its pivot point. It was controlled by the well known IDA-PBC controller which stabilize the system at its upward position (unstable equilibrium). The designed control law was based on some control parameters such as a proportional gain and a damping injection gain. The main investigation of this paper deals with the following question: Is the dynamic properties (stabilization) of the C-IWIP change when varying the control gains k_1 , k_2 , k_3 , and k_4 ?

Our main contribution consists of the use of the Hopf bifurcation theory and the center manifold theorem to show some additional dynamical behaviours of the inverted pendulum. We analyzed stability of the equilibrium point of the C-IWIP and then two stability conditions were developed. In addition, we determined the existence condition of the Hopf bifurcation as a function of some gain parameters of the IDA-PBC and therefore the generation of periodic oscillations (limit cycles). We characterized the stability of such solutions analytically by knowing the sign of the first Lyapunov value at the bifurcation boundary. Furthermore, we proved the effectiveness of analytical results numerically (Hopf bifurcation detection and stable limit cycle location).

In this work, analytical and numerical results were developed when applying IDA-PBC to the IWIP. However, to look for stable limit cycles the same methodology can be easily used to other underactuated mechanical systems with the same controller or with other controllers. As a future direction, we look for designing a robust tracking controller for the IWIP with uncertain parameters and/or under external disturbances. In addition, bifurcation analysis based on hamiltonian systems can be investigated.
