Thanks
I thank the members of the jury for the enthusiasm they have accepted to review my thesis with. I thank my colleagues at LIRMM and IUT for their fruitful discussions and exchanges. I thank my many collaborators and co-authors that each taught me something new and valuable. I thank the GraphIK group for their long standing influence in my research, dating back to my first year of PhD. I thank my family for their education, support and love. I thank Coemina for always being so happy and sweet. Thanks to Julien for his insights and humour and his family for their kindness.

Introduction

1.1 Overview

My research interests are in the field of knowledge representation and reasoning (KRR). During and since my PhD (throughout my post-doc and lectureship) I have investigated graph-based KRR languages applied in different Artificial Intelligence (AI) fields. Syntactically, the objects I am interested in are graphs. Semantically these graphs represent different subsets of logics such that the logic operations are sound and complete with graph operations. This adds logical background to the well-known modelling capacity of graphs. In the next section, I put in context this research vision with respect to my work.

1.2 Context

During my PhD the logics subset I focused on is the existential, positive fragment of First Order Logic (FOL). Conceptual Graphs [57] are one labelled bipartite graph representation of such logic. Logical subsumption can be translated (in a sound and complete manner) into labelled graph homomorphism, called projection. My contribution looked at improving both the (1) reasoning efficiency of such graphs and (2) their expressivity. Regarding reasoning I have proposed a projection optimisation based on the reduction of the labelled homomorphism into a max clique problem. Regarding the Conceptual Graphs expressivity I looked into their employability in Natural Language Processing, Multi-Agents Systems and the Semantic Web.

In Natural Language Processing I have investigated the Generation of Referring Expressions, where one is interested in obtaining a unique description of an object in a scene. Representing this problem using Conceptual Graphs allowed a clear contribution in terms of logical expressivity of the problem [27]. I have then extended Conceptual Graphs to represent multiple views on the same piece
of knowledge according to different agents interested in that knowledge. For the new syntactic object (a labelled tri-partite graph) I have proposed appropriate semantics that allow obtaining either a consensual subset of knowledge or different degrees of shared knowledge between agents [26]. Finally, Conceptual Graphs were used in order to express a summarised view of different knowledge bases in order to optimise distributed query answering. This summary (called a Knowledge Oriented Specification) could be done at different levels of detail and was expressed using another extension of Conceptual Graphs for representing hierarchical knowledge: Layered Conceptual Graphs. Once again, the corresponding semantics and reasoning mechanisms (based on graph operations) were provided [19].

During my PostDoc I continued this research in graph-based KRR and I further focused on Multi-Agents Systems and Semantic Web. The two application domains were given by the two European Projects I was working on.

The first project, HealthAgents: Agent-based Distributed Decision Support System for brain tumour diagnosis and prognosis(http://www.healthagents.net), was looking at creating a unified repository of brain tumour data shareable amongst the different medical partners in the project. The data compatibility was ensured by the use of a domain ontology [39]. The data interoperability was then ensured by the use of the Multi-Agents System framework designed as an abstraction of the several exchanges in the system [32]. My work involved the Semantic Web aspects of the project, notably building the domain ontology and linking the common domain ontology to the different medical databases available in the system. The proposed ontology was expressed in OWL and built using the Protege ontology building tool for W3C standardisation issues. The second contribution was a tool that allowed a semi-automatic map from the databases to the proposed ontology [21]. This graph-based tool was of great help to the domain experts. Finally, the security rights for the systems were formalised into a separate ontology using Conceptual Graphs to allow for both reasoning and domain expert feedback [65].

The second project I was involved in was Open Knowledge (http://www.openki.org). The purpose of the project was to investigate a simple Multi-Agents coordination language for the sharing of multi-media resources. My involvement in the project looked at Semantic Web aspects and Multi-Agents Systems aspects. More precisely, I was involved into adapting different standard multi-media ontologies for our project. I was also working on indexing aspects for ontology sharing [38]. From a Multi-Agents viewpoint one of the challenges involved in the project was the elicitation of agent preferences over resources. The agents had to be able to define preferences over a set of well defined resources. When these preferences are expressed using numerical values this problem corresponds to the problem of designing bidding languages for Combinatorial Auctions. In Combinatorial Auctions an auctioneer has a number of resources (objects) for sell, and the bidders will give numerical values on subsets of those objects. The Winner Determination is based on finding the allocation of objects to bidders that maximises the auctioneer’s revenue. It is
a NP-hard problem being equivalent to weighted set packing. In this context I have proposed a graph-based bidding language based (NET-bid) on an extension of network flows. This representation was also provided with according semantics where the max-flow on the aggregated NET-bids from all users corresponded to Winner Determination [20].

My PostDoc allowed me to continue my research interests in investigating graph-based KRR, either for FOL reasoning for the Semantic Web, or for reasoning in Multi-Agents Systems.

This line of work (graph-based KRR) was pursued further when arriving at LIRMM where the graph-based formalisms I have investigated can be viewed from two perspectives: a paradigm perspective and an application perspective. The two main paradigms (in the continuity of my PhD and PostDoc work) I have investigated are Multi-Agents Systems and ontological query answering. The application perspective was given by agronomy applications and bibliographic applications. The application domains allowed to merge the two paradigms of my research. I investigated the link between query answering under inconsistency and argumentation in the context of agronomy applications. I also looked at the problem of Multi-Agents knowledge allocation and information selling mechanism design. Currently I am investigating the link between inconsistency based reasoning and clustering semantics in the context of bibliographic knowledge bases.

In the remainder of the document I will detail the results obtained for each paradigm: conjunctive query answering and Multi-Agents systems, as well as results obtained at the intersection of these two AI domains. The conjunctive query answering work was in the continuity of my PhD work in conceptual graphs and extended towards three main directions to address current challenges in applications: large knowledge bases, inconsistent knowledge bases and query answer allocation. The Multi-Agents systems graph based knowledge representation and reasoning formalisms I investigated are centered around resource allocation (combinatorial auctions, coalition formation), norm representation and argumentation. The applications I have investigated are representation and reasoning in the bibliographical domain and representation and reasoning for agri-food chains.

It is also worthy to note that while at LIRMM I have co-initiated the GKR@IJCAI International Workshop Series (2009, 2011, 2013) reporting on graph-based KRR formalisms (that is, endowed with graph-based syntax and logical semantics). In 2010 I was also the program chair of the ICCS (International Conference on Conceptual Structures) conference, the main international conference focused on Conceptual Graphs and in 2014 I was the general chair of ICCS.

Let me conclude this section by noting that since 2010 I am part of the GraphIK INRIA group, a project team which gathers LIRMM members as well as INRA members. Since its creation I got involved with agronomy applications working closely with INRA colleagues on three projects: EcoBioCap, DUR DUR
and CEPIA AIC. The lessons learnt and the results obtained during this collaboration shaped my vision for my future research as explained in my research plan. Let us first enumerate the obtained results since 2008 onwards.

1.3 Thesis Organisation

I chose to present the research work I did in the past six years while at LIRMM, by the means of a collection of publications, each explained and put in context in the chapters at the beginning of the thesis.

Each chapter gives a quick and intuitive “story” of the research topics I am interested in. Then at the end of each chapter one or two significant papers are cited (and the reader directed towards the chapter that shows the papers in question). The papers are chosen given their potential to illustrate the point I was trying to bring across in the respective Section.

The chapters are grouped by: theory, application and future work. In Chapter 2, I present the main theoretical domain of research I have been interested in and namely graph based knowledge representation and reasoning. This Chapter is split in several Sections. In Section 2.2 I demonstrate labelled bipartite graphs, homomorphism and their application to query answering. In Section 2.3 I show network flows and their application to Multi-Agents resource allocation. In Section 2.4 I talk about argumentation graphs. Mixed domain results are then presented in Section 2.5 where the setting of Multi-Agents knowledge allocation is presented as well as in Section 2.6 where inconsistent query answering and argumentation equivalent semantics are revealed. All papers detailing the results of this Chapter are available in Chapter 5.

Chapter 3 presents the research projects I have participated in that involve non computing experts. This choice of presentation is due to the fact that such projects bring non negligible challenges in mixing applied and fundamental research that are not easy to overcome. In Section 3.2 I present an agronomy project aiming at improving packaging conception. In Section 3.3 and Section 3.4 I present two other agronomy projects, this times aimed at food challenges. Finally in Section3.5 I present a bibliographic data management project. All papers detailing the work presented in this Chapter are available in Chapter 6.

Chapter 4 concludes the thesis by presenting a research project aiming at developing a hybrid architecture for inconsistency handling in the agronomy domain.

Let me make a note by saying that this is a posteriori choice in presentation. Research is an online process and different interesting topics of research as well as application projects cannot be fully determined in advance. The presentation of work in this thesis and “how things happened” are not always identical. Going in more details of certain topics, while abandoning others that looked promising were not always research justified and depend greatly on the time, collaborators,
chance and funding opportunities. However, from my first year of PhD the main underlying topic of my work is the use of graph structures for knowledge representation and reasoning.
Chapter 2

Reasoning Using Graphs

2.1 Introduction

This chapter focuses on the core of my research so far and namely my interest in using graph-based formalisms for knowledge representation and reasoning. Knowledge representation and reasoning (KRR) has long been recognized as a central issue in Artificial Intelligence (AI). The development of effective techniques for KRR is a crucial aspect of successful intelligent systems. Different representation paradigms, as well as their use in dedicated reasoning systems, have been extensively studied in the past. The problem consists of how to encode human knowledge and reasoning by symbols that can be processed by a computer to obtain intelligent behavior.

New challenges, problems, and issues have emerged in the context of knowledge representation in AI, involving the logical manipulation of increasingly large information sets (see for example Semantic Web, BioInformatics and so on). Improvements in storage capacity and performance of computing infrastructure have also affected the nature of KRR systems, shifting their focus towards representational power and execution performance. Therefore, KRR research is faced with a challenge of developing knowledge representation structures optimized for large scale reasoning.

This new generation of KRR systems includes graph-based knowledge representation formalisms also appealing for their visual qualities. This is due to several factors:

- Firstly, graphs are simple mathematical objects (they only use elementary naive set theory notions such as elements, sets and relations) which have graphical representations (a set of points and lines connecting some pairs of points) and thus can be visualised.

- Secondly, there is a rich collection of efficient algorithms for processing graphs, thus graphs can be used as effective computational objects (they
are widely used, for instance, in Operational Research).

- Thirdly, graphs can be equipped with a logical semantics: the graph-based mechanisms they are provided with are sound and complete with respect to deduction in the assigned logic.

Furthermore, graph-based mechanisms can be explained to the user because they can be easily visualized on the graphs themselves. The results presented in this chapter will be put in context by the applications presented in Chapter 3. The results include the use of bipartite graphs and labelled graph homomorphisms for query answering (Section 2.2), network flow algorithms for multiagent resource allocation (Section 2.3) and argumentation graphs (Section 2.4). Results obtained at the intersection of the above fields are next presented. Section 2.5 shows how to use allocation techniques for query answering. Section 2.6 shows the link between inconsistent query answering techniques and argumentation.

Every section presents the general setting of the research question investigated. For more details, each section is illustrated by a representative paper in Chapter 5.

2.2 Query Answering and Graphs

One of the fundamental problems in KRR languages is entailment checking: is a given piece of knowledge entailed by other pieces of knowledge, for instance from a knowledge base (KB)? Another important problem is consistency checking: is a set of knowledge pieces (for instance the knowledge base itself) consistent, i.e., is it sure that nothing absurd can be entailed from it? The query answering problem asks for the set of answers to a query in the KB. In the special case of boolean queries (i.e., queries with a yes/no answer), it can be recast as entailment checking.

The ontology-based data access (OBDA) problem [43] takes a set of facts, an ontology and a conjunctive query and aims to find if there is an answer / all the answers to the query in the facts (eventually enriched by the ontology). The large number of ontologies and data sources defined on top of ontologies on the Web brought-on further challenges due to the data integration inherent to this setting: identity problems and large knowledge bases.

We consider these problems one by one in the remainder of the section. Section 2.2.1 discusses the advantages of using graph-based formalisms in the query answering context. Section 2.2.2 presents a generic platform for reasoning in the heterogeneous data setting of OBDA.
2.2.1 Conceptual Graphs Query Answering

Conceptual Graphs were introduced by John Sowa (cf. [56, 57]) as a diagrammatic system of logic with the purpose “to express meaning in a form that is logically precise, humanly readable, and computationally tractable” (cf. [57]). Throughout the remainder of this thesis we use the term “Conceptual Graphs” to denote the family of formalisms rooted in Sowa’s work and then enriched and further developed with a graph-based approach (cf. [16]).

In Conceptual Graphs all kinds of knowledge are encoded as graphs and thus can be visualised in a natural way:

- The vocabulary, which can be seen as a basic ontology (background knowledge) is composed of hierarchies of concepts and relations. These hierarchies can be visualized by their Hasse diagram, the usual way of drawing a partial order.

- All other kinds of knowledge are based on the representation of entities and their relationships. This representation is encoded by a labelled graph, with two kinds of nodes, respectively corresponding to entities and relations. Edges link entity nodes to relation nodes. These nodes are labelled by elements in the vocabulary.

These graphs have a semantics in first-order logic (FOL), i.e., a knowledge base can be translated into a set of first-order logical formulas. Reasoning tasks operate directly on the knowledge defined by the user and not on their translation into logical formulas. This is done by the means of labelled homomorphism between the knowledge base graph and the query graph. Stated in another way, the logical semantics is only used to formally ground the graph model, i.e., representation and reasoning mechanisms. This makes it possible to explain reasoning to the end-user because it can be visualized in a natural way on the pieces of knowledge he/she is familiar with. Would a logical prover be used on the logical translation of these pieces of knowledge to compute reasoning, reasoning would become a black box for the user and could not be explained. In the GraphIK group the Cogui tool has been developed: a graph based knowledge representation and reasoning editor implementing the Conceptual Graphs model.

In the paper “Visual Reasoning with Graph-based Mechanisms: the Good, the Better and the Best” by Michel Chein, Marie-Laure Mugnier and Madalina Croitoru [17] (available in Chapter 5) we show the main constructs of this language and the labelled graph homomorphism operation that allows to reason with Conceptual Graphs. We illustrate these operations on an annotation application and use Cogui in order to depict the graphs and illustrate the practical added value of using Conceptual Graphs.

In knowledge bases (KB), the open world assumption and the ability to express variables may lead to an answer redundancy problem. This problem oc-
curs when the returned answers are comparable. In collaboration with Michel Leclere and Nicolas Moreau we defined a framework to distinguish amongst answers. Our method is based on adding contextual knowledge extracted from the KB that allows clarification of the notion of redundancy between answers. Our work was done in a Conceptual Graphs setting and we provided a definition for the set of answers to be computed from a query, which ensures both properties of non-redundancy and completeness. A special case of this problem (when the answer is a concept node) corresponds to the problem of Generation of Referring Expressions (GRE) studied in the Conceptual Graphs context in [27], extended in this query answering setting.

In the paper “Distinguishing Answers in Conceptual Graph Knowledge Bases” by Nicolas Moreau, Michel Leclere, and Madalina Croitoru [46] (available in Chapter 5) we address the problem of query answers identification.

Let us mention that the RDF (Resource Description Framework) \(^1\) query language SPARQL offers a way to describe answers (by the DESCRIBE primitive) but this is not done according to semantically sound syntactic criteria. More generally RDF is close to our Conceptual Graphs framework. RDF has a graph-based representation, it is provided with a formal semantics and an associated entailment notion ([36], [37]), but it does not come with an effective reasoning mechanism, even less with a graph-based mechanism that would operate on the graph representation. It is worth mentioning at this point that a translation from RDF to Conceptual Graphs has been investigated in [7] and implemented in Cogui. This work has been taken further and, since the logical subset represented by Conceptual Graphs and RDF(S) overlaps, a generic approach to KRR was investigated. This is presented in the next Section 2.2.2

2.2.2 The ALASKA Platform

A problem particularly relevant in the context of multiple data/metadata sources is querying hybrid knowledge bases. In a hybrid knowledge base, each component may have its own formalism and its own reasoning mechanisms. Several languages have been proposed in the literature where the language expressiveness / tractability trade-off is justified by the needs of given applications. In description logics, the need to answer conjunctive queries has led to the definition and study of less expressive languages, such as the \(\mathcal{EL}\) [6] and DL-Lite families [13]. Properties of these languages were used to define profiles of the Semantic Web OWL 2 language (www.w3.org/TR/owl-overview).

When the above languages are used by real world applications, they are encoded in different data structures (e.g. relational databases, Triple Stores, graph structures). Justification for data structure choices include (1) storage speed (important for enriching the facts with the ontology) and (2) query efficiency. Therefore, deciding on what data structure is best for one’s application

-----

\(^1\)http://www.w3.org/TR/REC-rdf-syntax/
is a tedious task. While storing RDF(S) has been investigated from a database inspired structure [35], other logical languages did not have the same privilege. Even RDF(S), often seen as a graph, has not been thoroughly investigated from a ODBA perspective w.r.t. graph structures and emergence of graph databases in the NoSQL world.

ALASKA (acronym stands for Abstract and Logic-based Architecture for Storage systems and Knowledge bases Analysis) is a Java library dedicated to the storage and querying of large knowledge bases. It intends to be the foundation layer of our OBDA (Ontology Based Data Access) software developments. ALASKA has been built, first as part of a Masters thesis, and then part of the PhD of Bruno Paiva Lima da Silva (co-supervised with J.-F. Baget).

The ALASKA core (data structures and functions) is written independently of any language used by storage systems it will access. The advantage of using a subset of First Order Logic to maintain this genericity is to be able to access and retrieve data stored in any system by the means of a logically sound common data structure. Local encodings will be transformed and translated into any other representation language at any time. Basically, the abstract layer of ALASKA is a logical layer. Storage systems are used to store data that can be seen as sets of logical atoms. Wrappers are used to encode this atom according to the storage system paradigm. Whatever this storage system, ALASKA only reads and writes atoms or sets of atoms.

This abstract layer is not only used to read and write in an uniform manner into various storage systems, but also to process queries. A conjunctive query can also be seen as a set of atoms. ALASKA is able to transform them into, for example, SQL or SPARQL queries, to benefit from the native querying mechanism of specific storage systems. Moreover, a generic backtracking algorithm has been designed, that allows to process these queries on any of these storage systems. This backtrack relies upon elementary queries, that check whether or not a grounded atom is stored in the system, or enumerate all atoms that specialize a given one. This backtrack does not incorporate powerful optimizations and pruning features, since it is designed to process simple queries.

In the paper “ALASKA for Ontology Based Data Access” by Jean-Francois Baget, Madalina Cristoru and Bruno Paiva Lima da Silva [8] (available in Chapter 5) we give a demonstration of the ALASKA architecture.

### 2.3 Resource Allocation and Graphs

Representing agent preferences is another way for eliciting an agent’s knowledge. This can be further used in argumentation or normative systems (see Section 2.4). A preference is defined as a function from all the subsets of the set of resources / goals / pieces of knowledge over which the agent is expressing its preferences into a set of values. If the values are given numerically, the order re-
lation over preferences is total. If the values are not numeric, the (partial) order relation over preferences also has to be provided. The allocation of resources will then maximise the aggregated preferences of the agents. The Multi Agent Resource Allocation (MARA) setting has numerous applications in Multi-Agent Systems, notably for Combinatorial Auctions and Coalition Formation.

Combinatorial auctions (CAs) can be viewed as a method of allocating multiple heterogeneous goods among a number of individuals, each of whom can obtain not one but a bundle of goods. Bidding is the process of transmitting one’s valuation function over the set of goods on offer to the auctioneer. The communication language is called a bidding language and it plays a key role in both central aspects of the allocation problem: preference elicitation and winner-determination (WD). Several bidding languages for CAs have previously been proposed, arguably the most compelling of which allow bidders to explicitly represent the logical structure of their valuation over goods via standard logical operators (e.g., [47]).

We proposed in [20] a visual paradigm for representing bidding languages for combinatorial auctions based on generalised network flows (used to represent the bids) and, the interpretation of the WD as a fair aggregation of individual preferences making use of max flow algorithms. Our work on combinatorial auctions led me to take an interest in a very closely related field: coalitional games.

Coalitional games are theoretical constructs that capture opportunities for cooperation by explicitly allowing agents to take joint actions as primitives [40]. One of the key issues in multi-agent coalition formation is the Coalition Structure Generation (CSG) problem, which involves dividing the set of agents into subsets (i.e., coalitions) so that the overall efficiency of the system is maximised. Such a division is referred to as a coalition structure. This problem, which is extremely challenging due to the exponential size of the search space, has recently attracted considerable attention in the Multi-Agents System literature [54, 52, 51]. It is typically assumed that the coalitions within every coalition structure are disjoint, and that they cover the entire set of agents. Moreover, the input to the problem is typically represented using a characteristic function, which assigns a value for every possible coalition, representing its performance.

The same network flow based representation was used as the backbone to a Generalised Network Flow representation for Coalition Games and gave the CF-NETs. Specifically, this representation is based on the observation that the coalition formation process can be viewed as the problem of directing the flow through a network where every edge has certain capacity constraints. We show that our new way of representing this process is intuitive, fully expressive, and allows for representing certain patterns in a significantly more concise manner compared to the conventional approach.

In the paper “Coalitional Games via Network Flows” by Talal Rahwan, Tri-Dung Nguyen, Tomasz P. Michalak, Maria Polukarov, Madalina Croitoru and Nicholas R. Jennings [53] (available in Chap
ter 5) we show that CF-NETs have the flexibility to represent characteristic function games, coalitional games with overlapping coalitions, and coalitional games with identical agents.

2.4 Argumentation, Norms and Graphs

As explained in Section 2.1, the Ontology Based Data Access (OBDA) setting can yield to data inconsistency. Argumentation theory is a well-known method for dealing with inconsistent knowledge. Logic-based argumentation considers constructing arguments from inconsistent knowledge bases, identifying attacks between them and selecting acceptable arguments and their conclusions. In order to know which arguments to accept, one applies a particular argumentation semantics.

When arguing about a course of actions to pursue, agents can introduce a multitude of arguments aimed at supporting their position and undermining other possible views. When represented in some underlying logic, formal argumentation theory provides the tools to reason about these arguments, allowing one to, for example, identify a consistent set of arguments and the course of actions they advocate. A core question that arises is what arguments an agent should utter in order to achieve these goals. This dialogue planning problem is, in most cases, computationally challenging, and work on argument strategy [3, 41, 48, 55] has identified heuristics which are used to guide an agent’s utterances.

In [22] we sought to use a graph-based method to identify all arguments that an agent must advance at a specific point in time. The salient point of our work was that the argument structure was translated into a network flow structure, and then we could utilise graph operations (max flow) in order to calculate the appropriate set of arguments to advance. This paper, “Information Revelation Strategies in Abstract Argument Frameworks Using Graph Based Reasoning,” by Madalina Croitoru and Nir Oren is available in Chapter 5.

The argumentation work also led me to investigate normative systems. The reason for investigating norms stemmed from the fact that some of the agents’ arguments could have a different impact rather than other agents. These agents could impose norms of behaviour on all agents that should be respected. In normative systems, the norms to be adhered by all agents are represented using tuples of First Order Logic formulae. These norms apply on all agents and the question is: at a given time and for a given state of the world what norms are violated. In the paper “Graphical norms via conceptual graphs” by Madalina Croitoru, Nir Oren, Simon Miles and Mike Luch [23] (available in Chapter 5) we looked into representing the norm structure using a graph-based KRR where normative reasoning corresponds to graph-based operations on these graphs. This work has been extended for reasoning with different kind of norms (permissions, obli-
2.5 Resource Allocation for Query Answering

The assumption behind semantic data integration and querying is that different agents accessing the integrated data repository will have equal interest in the querying results. In the setting of the query answering problem the multiplicity of knowledge requesters was simply regarded as a simple extension of the individual case. This assumption does not always hold in practical applications where the requesters are in direct competition for knowledge (newsagents, military applications). This is not always true in a data sensitive scenario where the knowledge provider might want to allocate the query answers to the agents based on their valuations. Furthermore, the agents might want some information exclusively (and thus offer a valuation that allows it) while others might want it shared. To this end, new mechanisms of allocation of query answers are needed.

We draw from the fields of query answering in information systems and multi agent resource allocation and propose the multi agent knowledge allocation setting (MAKA). We have proposed a graph based method, inspired by network flows, for solving it. These results were investigated jointly with Dr. Sebastian Rudolph from University of Dresden. In the paper “Exclusivity-based allocation of knowledge” by Madalina Croitoru and Sebastian Rudolph [25] (available in Chapter 5) we define a bidding language based on exclusivity-annotated conjunctive queries and show a way to succinctly translate the allocation problem into a graph structure allowing to employ a wide range of constraint solving techniques to find the optimal allocation.

I also investigated the mechanism design aspects of such valuations in collaboration with Dr. Jannis Vetsikas from the University of Athens. If we were to apply well known auction mechanisms to selling pieces of information that can be shared, hence are infinitely copied, no profit would be made; this would happen because competition is what drives the prices up and offering more items - here infinite - than buyers essentially removes any competition in this setting. And yet getting profit is usually the first goal of a seller. Moreover, the mechanisms for auctioning this kind of goods need to be incentive compatible, meaning that bidders would have an incentive to lie which would break down the mechanism.

In the paper “How much should you pay for information?” by Ioannis Vetsikas and Madalina Croitoru [64] (available in Chapter 5) we present and analyse several incentive compatible mechanisms for selling a single sharable good to bidders who are happy to share it, aiming at creating competition by restricting the number of winners.
2.6 Argumentation for Query Answering

As previously mentioned, argumentation theory is a well-known method for dealing with inconsistent knowledge [9, 2]. Logic-based argumentation [10] considers constructing arguments from inconsistent knowledge bases, identifying attacks between them and selecting acceptable arguments and their conclusions. Recently, this question was also considered in the OBDA case [42, 11] where maximal consistent subsets of the KB, called repairs, are then considered and different semantics (based on classical entailment on repairs) are proposed in order to compute the set of accepted formulae. Once the repairs calculated, there are different ways to calculate the set of facts that follow from an inconsistent knowledge base. For example, we may want to accept a query if it is entailed in all repairs (AR semantics). Another possibility is to check whether the query is entailed from the intersection of closed repairs (ICR semantics). Finally, another possibility is to consider the intersection of all repairs (IAR semantics).

Our work starts from the observation that both inconsistent ontological KB query answering and instantiated argumentation theory deal with the same issue, which is reasoning under inconsistent information. Furthermore, both communities have several mechanisms to select acceptable conclusions. Natural questions one could immediately ask are: Is there a link between the semantics used in inconsistent ontological KB query answering and those from argumentation theory? Is it possible to instantiate Dung’s abstract argumentation theory in a way to implement the existing semantics from ontological KB query answering? If so, which semantics from ontological KB query answering correspond to which semantics from argumentation theory? Does the proposed instantiation of Dung’s abstract argumentation theory satisfy the rationality postulates [15]?

There are several benefits from answering those questions. First, it would allow to import some results from argumentation theory to ontological query answering and vice versa, and more generally open the way to the Argumentation Web [50]. Second, it might be possible to use these results in order to explain to users how repairs are constructed and why a particular conclusion holds in a given semantics by constructing and evaluating arguments in favour of different conclusions [30]. Also, on a more theoretical side, proving a link between argumentation theory and the results in the knowledge representation community would be a step forward in understanding the expressibility of Dung’s abstract theory for logic-based argumentation [63].

This work has been done jointly with Dr. Srdjan Vesic from CRIL, Univ. Artois. In the paper “What Can Argumentation Do for Inconsistent Ontology Query Answering?” by Madalina Croitoru and Srdjan Vesic [28] (available in Chapter 5) we show that it is possible to instantiate Dung’s abstract argumentation theory in a way to deal with inconsistency in an ontological knowledge base (KB). Second, we formally prove the links between the semantics from ontological KB query an-
swering and those from argumentation theory: ICR semantics corresponds to sceptical acceptance under stable or preferred argumentation semantics, AR semantics corresponds to universal acceptance under stable / preferred argumentation semantics and IAR semantics corresponds to acceptance under grounded argumentation semantics. Third, we show that the instantiation we define satisfies the rationality postulates.

The results allowed to use results from argumentation theory in order to explain reasoning under inconsistency in knowledge bases. This topic is at the center of the thesis of Abdallah Arioua (co-supervised with P. Buche and J. Fortin) and first results have already been showed. In the paper “On Conceptual Graphs and Explanation of Query Answering Under Inconsistency” by Abdallah Arioua, Nouredine Tamani and Madalina Croitoru [4] (available in Chapter 5) we present query answering explanation strategies inspired from the link between the OBDA inconsistent-tolerant semantics and argumentation acceptance semantics.
Chapter 3

Inter-Disciplinary Projects

3.1 Introduction

In this chapter I detail the research projects I have been involved in since my arrival at LIRMM in 2008. I will pay special attention to the interdisciplinary projects, where at least one of the main participants is not a computing science center. I believe that applying research in practice is a major challenge of current Artificial Intelligence (I only focus on Artificial Intelligence since it is my primary field of expertise). The time and expertise needed to develop both aspects and the incertitude inherent to research and development make this a difficult task to fulfill.

In this chapter I will detail three projects within an agronomy scenario. One project looks at packaging aspects (Section 3.2) while the other two focus on food aspects (Section 3.4 and Section 3.3). While the project presented in Section 3.4 has only started in 2014, I think it is important to show the first results that were obtained. The fourth project I will detail is a project made in collaboration with bibliographic data experts presented in Section 3.5.

3.2 EU FP7 EcoBioCap

Conceiving food packagings that are taking into account all factors from different stakeholders in the production chain is an exciting, timely and important challenge to face. Changes such as (1) growing demands for ready to eat foods, (2) globalisation of the food business, (3) limiting the amount of waste generated by packagings are driving a search for innovative ways to package foods while maintaining quality, freshness, and safety. Packaging conception should take into account many aspects. Criteria such as visual appeal, labelling norm compliance, stability, safety, environmental impact and cost-effectiveness have to be considered before full exploitation. However, taking into account all cri-
teria can yield contradictory actions. Domain experts cannot express complete rules (along with the many exceptions of such rules) due to the complexity of the knowledge. Therefore, when trying to reason with the incompletely elicited knowledge available numerous inconsistencies occur and the important problem underlying the food packaging conception comes down on to how to reason under inconsistency and incompleteness with non monotonic knowledge.

Within the framework of the European project EcoBioCap (www.ecobiocap.eu) about the design of next generation packagings using advanced composite structures based on constituents derived from the food industry, we developed a Decision Support System (DSS) for packaging material selection. The DSS is made of two parts: (i) a flexible querying process which is based on a bipolar querying approach [29] dealing with imprecise data corresponding to the characteristics related to the food product to pack like the optimal permeance, the dimension of the packaging, its shape, etc., and (ii) an argumentation process which aims at aggregating several stakeholders requirements expressed as simple text arguments, to enrich the querying process by stakeholders’ justified preferences. The former implements a database containing the respiration parameters of the packed food, and a second database storing the characteristics of packaging materials ($O_2$ and $CO_2$ permeance, biodegradability, transparency, etc.). The user can also specify some preferences such as the preferred storage temperature, dimensions of the packaging, etc, which could be mandatory or optional. This part of the software combines these inputs to compute the optimal permeance which guarantees the best shelf life for the packed food. Then, this optimal permeance are mixed with other user preference to form a bipolar query addressed to the packaging database. The returned list of packaging is ranked from the most to the least relevant one with regard to the expressed preferences.

For example, in order to pack cheese, researchers focus on the permeance properties in their following argument: “a wheat gluten based material packaging is suitable for cheese because it offers a good atmosphere control”, and cheese producers can retort with the following counter-argument “a gluten layer cannot put in contact with cheese since the bacteria in the crust would degrade the packaging”, considering here the interaction with the packed food aspect. As we see packagings have to be selected according to several aspects or criteria (permeance, interaction with the packed food, end of life, etc.), highlighted by the expressed stakeholders’ arguments. To collect the user preferences, different surveys have been carried out among the stakeholders involved in the design of packaging: researchers, packaging industries, food producers, consumers, etc. The asked questions are about cost, end of life, biodegradability, the use of nanoparticles in the packaging, etc. For each criterion expressed through surveys, the stakeholders identified its importance, indicated the preferred values, and the reasons that justify their choice. The importance permits to give a priority to criteria over others, used in the bipolar approach considering mandatory and optional preferences. For instance, sanitary criteria ensuring a good preservation of the packed food are naturally more important than the color or the

24
transparency of the packaging. The values, in the other hand, can be easily used as predicates in the bipolar query.

Please note that the problem at hand does not simply consist in addressing a multi-criteria optimization problem [12]: the domain experts would need to be able to justify why a certain packaging (or set of possible packagings) are chosen.

Work in this project has been carried out jointly with members of IATE working on packaging conception. A joint publication (as seen below) with the experts was produced in which we detail the architecture and use of the module implemented. Part of the project, jointly with Patrice Buche, I have co-supervised Nouredine Tamani (a post-doctoral researcher) and Patricio Mosse (a Master student and then a programming assistant).

To be able to model this kind of reasoning, we need a structured format for arguments in which it is possible to express the involved concepts and rules modeling the semantics behind the text. We rely in this work on a subset of a logical structured argumentation system which corresponds to the smallest common subset of approaches presented in [1, 49, 43]. Such structured argumentation system (i) allows the expression of logical arguments as a combination of facts and inference rules, (ii) defines attacks and defeat relations between arguments based on a logical conflict notion.

The reasoning process underlying arguments is related to a domain which can be easily set-based interpreted. It is then possible to consider certain subsets of description logics to define concepts and rules forming arguments, for their well known trade off between a good level of expressivity and computational decidability. Here we make a choice to use the DLR-Lite description logic [18, 14] since it also allows a direct connection to a database schema and relational tables needed in the second step of querying. Concepts are defined by m-ary relations connected to sets of tuples from a database and rules can be expressed by natural subsumption between concepts. In this way, the interpretation of the arguments is closely related to the domain of definition of a database, and the result of the argumentation process can be directly harnessed in the querying phase. For each criterion expressed through surveys, the stakeholders identified the reasons that justify their choice which were modeled as arguments pros or cons some choices or values. They can justify why a packaging is better than another and can be then used to enrich the bipolar querying system. So, we detail in the next sections how arguments are logically modelled within a structured argumentation system and how the delivered justified conclusions can be used in the querying process. In Chapter 6 we show two papers:

- The paper “Conflicting Viewpoint Relational Database Querying: An Argumentation Approach” by Nouredine Tamani, Madalina Croitoru and Patrice Buche [60] (available in Chapter 6) summarises the use of argumentation in EcoBioCap and provides related theoretical work pointers.
In the paper “Eco-Efficient Packaging Material Selection for Fresh Produce: Industrial Session” by Nouredine Tamani, Patrício Mosse, Madalina Croitoru, Patrice Buche, Valerie Guillaud, Carole Guillaume and Nathalie Gontard [61] (available in Chapter 6) we show the architecture of our DSS based on argumentation.

3.3 INRA CEPIA AIC T80 - T65

The case of study considered in this project relates to the debate around the change of ash content in flour used for common French bread. Various actors of the agronomy sector are concerned, in particular the Ministry for Health through its recommendations within the framework of the PNSS (“National Program for Nutrition and Health”), the millers, the bakers, the nutritionists and the consumers.

The PNSS recommends to privilege the whole-grain cereal products and in particular to pass to a common bread of T80 type, i.e., made with flour containing an ash content (mineral matter rate) of 0.8%, instead of the type T65 (0.65% of mineral matter) currently used. Increasing the ash content comes down to using a more complete flour, since mineral matter is concentrated in the peripheral layers of the wheat grain, as well as a good amount of components of nutritional interest (vitamins, fibres). However, the peripheral layers of the grain are also exposed to the phytosanitary products, which does not make them advisable from a health point of view, unless one uses organic flour.

Other arguments (and of various nature) are in favour or discredit whole-grain bread. From an organoleptic point of view for example, the bread loses out in its “being crusty”. From a nutritional point of view, the argument according to which the fibres are beneficial for health is discussed, some fibres could irritate the digestive system. From an economic point of view, the bakers fear selling less bread, because whole-grain bread increases satiety - which is beneficial from a nutritional point of view, for the regulation of the appetite and the fight against food imbalances and pathologies. However whole-grain bread requires also less flour and more water for its production, thus reducing the cost. The millers also fear a decrease in the quality of the technical methods used in the flour production.

Beyond the polemic on the choice between two alternatives (T65 or T80), one can take the debate further by distinguishing the various points of view concerned, identifying the desirable target characteristics, estimating the means of reaching that point. The contribution of our work is showing how using argumentation can help towards such practical goals.

Reverse engineering is known to be challenging from a methodological viewpoint due to the difficulty of defining the specifications for the expected finished product. The desired quality criteria are multiple, questionable, and not necessarily compatible. Furthermore, the impact of different steps of food processing
and their order is not completely known. Some steps are more studied than others, several successive steps can have opposite effects (or unknown effects), the target criteria may be outside of the characteristics of products.

We proposed a methodology combining the reverse engineering and logical based argumentation for selecting the actions to take towards the agronomy application at hand. We used the Conceptual Graphs knowledge representation and reasoning formalism (see Chapter 2 and the logical argumentation instantiation of [28]).

The set of goals, viewpoints, as well as the knowledge associated with the goals /viewpoints is elicited either by the means of interviews with the domain experts or manually from different scientific papers. This step of the application has been the most time consuming but the most important. If the knowledge elicited is not complete, sound or precise the outcome of the system is compromised. Then, based on the knowledge elicited from the knowledge experts and their goals, we enrich the knowledge bases using reverse engineering (implemented using backwards chaining algorithms i.e., algorithms that work up from the query, using the rules, to enrich the set of facts in the knowledge base). Putting together the enriched knowledge bases obtained by backwards chaining from the different goals will lead to inconsistencies. The argumentation process is used at this step and the extensions yield by the applications computed. Based on the extensions and the associated viewpoints we can use voting functions to determine the application choice of viewpoints.

The evaluation of the system implemented was done via a series of interviews with domain experts. The above knowledge and reasoning procedures were implemented using the Cogui knowledge representation tool with an extension of 2000 lines of supplemental code. Three experts have validated our approach: two researchers in food science and cereal technologies of the French national institute of agronomic research, specialists respectively of the grain-to-flour transformation process and of the breadmaking process, and one industrial expert - the president of the French National Institute of Bread and Pastry.

Two interests of the approach were more particularly highlighted. They concern cognitive considerations. First, experts were conscious that the elicitation procedure was done according to their thought processes. The system was thus able to restitute the knowledge in a different manner than the experts usually do. Secondly, from a problem that could initially seem simple, the experts realised that it covered a huge complexity that a human mind could hardly address alone. The tool is currently available to them under restricted access.

In the paper “Decision support for agri-food chains: A reverse engineering argumentation-based approach” by Rallou Thomopoulos, Madalina Croitoru and Noureddine Tamani [62] (available in Chapter 6) we fully describe the technical details and knowledge represented within this application.
3.4 French ANR DUR-DUR

The ANR DURDUR project aims at re-organising the durum what agrifood chain in the aim of lowering pesticide use and increasing productivity and wheat disease resistance. The project only started at the beginning of 2014 thus the domain information is still scarce. This is the reason why the approach presented so far (and under implementation) is purely theoretical. But the approach addresses a key aspect of knowledge capitalisation in this setting: how to explain knowledge reasoning results to domain experts, not necessarily logicians. The task is even more daunting because the knowledge used as a backbone for reasoning is inconsistent and thus different inconsistency tolerant mechanisms need to be employed in order to perform deduction.

We address the problem of providing explanation facilities for query answering (query acceptance and query failure) in the ontology-based data access (OBDA) setting under inconsistency-tolerant semantics (explained in Chapter 2). Query answering under these semantics may not be intuitively straightforward and can lead to loss of user’s trust and satisfaction, affecting the system’s usability [44]. Moreover, explanation facilities should not just account for user’s “Why Q?” question (why a query holds under a given inconsistency-tolerant semantics) but also for question like “Why not Q?” (why a query does not hold under a given semantics).

Given an inconsistent OBDA setting equipped with an inconsistency-tolerant semantics and given a boolean conjunctive query Q we consider two query answering problems and namely: (RQ₁) “Why does Q hold under such semantics?” and (RQ₂) “Why Q does not hold under such semantics?”. Knowledge base explanation that takes the form of ‘Justification’ is more effective then other type of explanation (i.e. Line of Reasoning and Strategy). Justification according to the survey is considered as “the most effective type of explanation”. This type of explanation aims at showing the reason why certain conclusion has drawn in particular circumstance. Following this result, we consider the logical instantiation of an argumentation framework for OBDA and exploit the equivalence between inconsistency tolerant semantics and argumentation semantics. The explanation takes the form of a dialogue between the User and the Reasoner with the purpose of explaining the query failure. At each level of the dialogue, we use language-based introduced primitives such as clarification and deepening to further refine the answer.

In the paper “Query Failure Explanation in Inconsistent Knowledge Bases Using Argumentation” by Abdallah Arioua, Nouredine Tamani, Madalina Croitoru and Patrice Buche [5] (available in Chapter 6) we provide the technical details of this promising approach.
3.5 French ANR Qualinca

The SUDOC (catalogue du Systeme Universitaire de Documentation) is a large bibliographical knowledge base managed by ABES (Agence Bibliographique de l'Enseignement Supérieur). The SUDOC contains \( \approx 10,000,000 \) document descriptions, and \( \approx 2,000,000 \) person descriptions. A person description possesses some attributes (ppn\(^1\), appellation set, date of birth...). A document description also possesses some attributes (title, ppn, language, publication date...) and a link to a person description. A link is labeled by a role (such as author, illustrator or thesis advisor) and means that the person has participated as the labelled role to the document.

One of the most important tasks for ABES experts is to reference a new book in SUDOC. To this end, the expert has to register the title, number of pages, types of publication domains, language, publication date, and so on. This new description represents the physical books in the librarian hands which he/she is registering. He/she also has to register people which participated to the book's creation. In order to do that, for each contributor, he/she selects every person description which has an appellation similar to the book contributor. Unfortunately, there is not that much information in person descriptions because the librarian politics is to give minimal information, solely in order to distinguish two person descriptions which have the same appellation, and nothing more (they reference books, not people). So the librarian has to look at document description which are linked in order to see whether the book in his/her hands seems to be a part of the bibliography of a particular candidate. If it is the case, he/she links the new document description to this candidate and looks at the next unlinked contributor. If there is no good candidate, he/she creates a new person description to represent the contributor.

This task is fastidious because it is possible to have a lot of candidates for a single contributor (as much as 27 for a contributor named Bernard Alain). This creates errors, which in turn can create new errors since linking is an incremental process. In order to help experts to repair erroneous links, we proposed two partitioning semantics in [33] which enable us to detect erroneous links in bibliographic knowledge bases. A partitioning semantics evaluates and compares partitions of elements couples (person description, document description).

In the paper “An analysis of the SUDOC bibliographic knowledge base from a link validity viewpoint” by Lea Guizol, Olivier Rousseaux, Madalina Croitoru, Yann Nicolas and Aline Le Provost [34] (available in Chapter 6) we practically evaluate the qualitative results of partitioning semantics on a real SUDOC sample. Let us mention that this work has been done within the PhD thesis of Lea Guizol supervised by Madalina Croitoru.

\(^1\)A ppn identifies a description.
Chapter 4

Perspectives

4.1 Introduction

This chapter details the current and future research activities I currently work on and plan to undertake next. My long term research plan is to build an unified platform for knowledge representation and reasoning in presence of inconsistency. I plan to test and evaluate the practical need of this platform in the agronomy domain.

This chapter is structured as follows. I start by presenting the specificities of the agronomy domain and why reasoning in presence of inconsistency is a key aspect of knowledge representation and reasoning in this field (Section 4.2). A project for such a platform is then presented in Section 4.3. Of course this platform will evolve in the course of the next years as discussed in the final section of the chapter, Section 4.4.

4.2 Application Setting

A privileged domain application of my work in the past two years has been agronomy. The choice of the agronomy domain as a focus is motivated both by the local context of INRIA GraphIK project group (some members of GraphIK are also members of the UMR IATE) and by its adequation in terms of research challenges. The challenges in the agronomy field seem to be particularly well-adapted to artificial intelligence techniques. So far there are no mathematical models available to solve the problems related to the quality of agrifood chains. Their specificity is that such problems need to be stated at a conceptual level. Furthermore, solving these problems requires an integrated approach that takes into account expert knowledge, which is typically symbolic, as well as numeric data, vague or uncertain information and multi-granularity knowledge.

In agrifood chains, the products traditionally go through the intermediate
stages of processing, storage, transport, packaging and reach the consumer (the
demand) from the producer (the supply). Due to an increase in quality con-
straints, several parties are involved in production process, such as consumers,
industrials, health and sanitary authorities, etc. expressing their requirements
on the final product as different point of views which could be conflicting. We
accept that several complementary points of view - possibly contradictory - can
be expressed (nutritional, environmental, taste, etc.). We then need to assess
their compatibility (or incompatibility) and identify solutions satisfying a max-
imum set of viewpoints.

Eliciting (gathering knowledge from users) knowledge in such setting is a
long process involving multiple and potentially conflicting viewpoints and ac-
tors. Knowledge representation needs to follow a language which is easily in-
teroperable with other potentially useful knowledge repositories of the studied
field. One of the main aspects of such representation effort is the capitalisation
need. Choosing the knowledge representation language adapted for the applica-
tion at hand in such way that the represented knowledge can benefit from
similar efforts, and that it can be further re-used by other applications is an
important point to consider in this setting.

Once the knowledge representation step over, reasoning capabilities should
be made available. Reasoning in presence of inconsistency can be dealt with in
two ways: fixing the inconsistency or living with the inconsistency.

The first alternative includes several methods from lifting to a more general
knowledge representation language to deleting pieces of knowledge or adding
pieces of knowledge. Please note that deleting pieces of knowledge, in certain
cases is not ideal for our application since it means deleting some knowledge
that the experts purposely represented in the system.

The second case presents many possibilities. So far, as methods of reasoning
in presence of inconsistency, I have considered argumentation, belief revision
and default logics. Each come with their own specific inconsistency handling
use case: argumentation has been extensively investigated as an inconsistency
handling framework due to its explanatory power, belief revision considers the
scenario of adding / deleting information while default logics concern incomplete
information (and thus this kind of method could be used in tight coupling with
the first method).

We will show in the next section how we envisage to build a knowledge rep-
resentation and reasoning platform that will make use of all these methods in a
particular logically instantiated case equivalent to Conceptual Graphs. Fur-
thermore, reasoning will be used in order to direct the knowledge elicitation process
and, when possible, lift some inconsistencies.
4.3 Unified Inconsistency Reasoning

*The primary and innovational aim of my project is to provide an unified methodology of elicitation and reasoning in presence of data inconsistency.*

This will be done by two means:

- Eliciting new knowledge to lift, if possible, the inconsistency. By the means of automatically generated explanations for such inconsistencies – targeting the inconsistent subsets of knowledge (conflict sets) – new knowledge can be elicited from the end user. The new knowledge needs to be incorporated in the knowledge base in a semantic and principled manner.
- Answer queries in presence of such inconsistencies and explain the query answers.

Such approach is based on a given knowledge representation and reasoning logical language. I plan to use the logical subset equivalent to Conceptual Graphs given their graph-based representation and reasoning mechanisms (and the interaction with other Semantic Web languages via the Cogui platform). The reasoning in presence of inconsistency can use several methods such as argumentation, belief revision and non-monotonic logics such as default logics. Let us highlight at this point that the elicitation based on the inconsistency can only happen if the process is guided by a high level view point reasoning (which in turn can make use of argumentation techniques) and that will guide the belief revision process. A high level overview of the proposed project is given in Figure 4.1.

Before such tool can be built one must first face important foundational challenges:

- Knowledge Acquisition and Elicitation: Find a semi automatic method for extracting different knowledge (rules, facts, constraints) from controlled natural language text entered by domain experts.
- Given a knowledge base, devise algorithms to efficiently identify its minimal inconsistent subsets.
- Propose explanation strategies in knowledge bases and evaluate their practical appeal to domain experts.
- Use the explanation for the inconsistency as the basis to elicitate new knowledge.
- Incorporate new knowledge into the system and assess consistency.
- Reason (eventually in presence of inconsistency) and explain query answering results.
We started this year to develop Hyena (HYbrid knowlEdge reasoNing and representAtion), a hybrid platform which allows to elicit, represent, reason with and explain inconsistency in Semantic Web knowledge bases.

We follow a rule-based representation of ontologies and base our work on the Alaska platform (see Section 2.2.2). Hyena relies on five modules (depicted in Figure 4.2):

1. The Knowledge Base Module. The user imports a Knowledge Base using the ALASKA Manager, which stores it in an ALASKA project. Users import Knowledge Bases from different files: Facts are imported from RDF and N3 files, while Rules and Negative Constraints are imported from Datalog files.

2. The Visualization Module. The Visualization Module, which uses the popular Graphviz library, displays the knowledge base in a graphical manner on the screen.

3. The Belief Revision Module. The Belief Revision Module allows updating the (possibly inconsistent) knowledge base.

5. The Explanation Module. The Explanation Module receives the query and one result, and analyses the (possibly inconsistent) Knowledge Base to understand how that result was reached.
In Figure 4.3 we depict the workflow of the Hyena architecture.

The user interacts with Hyena. In order to reason with knowledge a high level view point, filtering is needed (this is needed in complex domains where the multitude of viewpoints and the inherent conflicting information they bring makes the user querying task confusing). After this stage, reasoning in presence of inconsistency is performed and explained. This reasoning is based on alternative methods such as non-monotonic specially dedicated knowledge, argumentation and belief revision. The latter will help update the knowledge base with information the user might want to bring based on the provided explanations.

Two recent theoretical results should be reminded. First, together with Jerome Fortin and Abdallah Aroua from the GraphIK group we investigated an efficient (with respect to time and space complexity) mapping between inconsistent ontological knowledge bases (expressed in a general rule-based language) and a class of default theories (semi-monotonic, precisely prerequisite-free closed normal default theories). We formally proved the equivalence between the inconsistency-tolerant semantics in OBDA and inference in Default Logic as well the property of semi-monotonicity for inconsistency-tolerant semantics that can serve as a basis for an anytime algorithm for query answering. This means that default logic inspired algorithms for repair and inconsistency tolerant se-
mantics are possible. Second, together with Ricardo Rodriguez from University of Buenos Aires we have been studying the link between belief revision and inconsistency tolerant semantics in [24]. We showed how to get first results towards an axiomatic characterisation of certain semantics (see Chapter 2 for their definitions). The axiomatisation was done by covering the semantics using known consolidation operators from belief revision.

4.4 Future Directions

The immediate line of work envisaged for Hyena is developing and analysing properties of query answering explanation algorithms. Eventual optimisations of these algorithms could be envisaged, for example when considering preferences between sets of atoms. Such preferences could be interpreted as priorities over the knowledge base sets imported in Hyena, or by considering an ordering over viewpoints of experts. Then, if the preference relation satisfies certain properties one can show interesting properties of inconsistency tolerant semantics. This last line of research is investigated with Slawek Staworko from University of Lille.

Preferences could also be numerical and the use of fuzzy logics in this setting could bring interesting results. While the use of a fuzzy logic for low expressiveness description logics has already been investigated in EcoBioCap [58, 59] extending these results to the more expressive fragment of logics could bring promising research avenues. Furthermore, the tool developed in EcoBioCap could be extended to reason with expressive rules and thus be incorporated in the Hyena workflow.
Figure 4.4 shows an example of how Cogui, the explanation algorithms and the extension of EcoBioCap tool could function together for representation, reasoning and elicitation of knowledge.

![Figure 4.4: Hyena Workflow Enriched with Tools](image)

As previously mentioned Hyena is a long term project which interacts with other projects developed in the GraphIK and Axe 5 at IATE groups. Hyena also behaves as complement to the capitalisation tools developed in Axe 5. Therefore in the future, special attention should be given to the knowledge representation and reasoning formalism and their interoperability properties. This should allow for interoperability with other Semantic Web tools as well as tools developed in the group.

Let me conclude by re-stating the observation made in the introduction of this thesis: research is an online process that, inevitably, contains a part of unknown and surprise. While the research project I presented is something that I am fully dedicated and committed to, in ten years changes in Artificial Intelligence tools and paradigms might change its methodology. However, I am confident in saying that reasoning in presence of inconsistency and elicitation are and will be at the core of knowledge representation and reasoning challenges in the years to come.

Papers on Graph Reasoning
Visual Reasoning with Graph-based Mechanisms: 
the Good, the Better and the Best

Michel Chein, Marie-Laure Mugnier, Madalina Croitoru

E-mail: {chein,mugnier,croitoru}@lirmm.fr

Abstract
This paper presents a graph-based knowledge representation and reasoning language. This 
language benefits from an important syntactic operation, which is called a graph homomorphism. 
This operation is sound and complete with respect to logical deduction. Hence, it is possible 
to do logical reasoning without using the language of logic but only graphical, thus visual, notions. 
This paper presents the main knowledge constructs of this language, elementary graph-
based reasoning mechanisms, as well as the graph homomorphism, which encompasses all these 
elementary transformations in one global step. We put our work in context by presenting a 
concrete semantic annotation application example.

1 Introduction

Knowledge Representation and Reasoning. Knowledge representation and reasoning 
(KR) has long been recognized as a central issue in Artificial Intelligence (AI). Very generally 
speaking, the problem is how to encode human knowledge and reasoning by symbols that can 
be processed by a computer to obtain intelligent behavior. In general, Artificial Intelligence 
is concerned with qualitative, rather than quantitative, problem solving. As a basic building 
block of AI applications, a knowledge representation formalism should reflect this idea by 
supporting reasoning instead of calculation. This is done by organizing the knowledge into an 
easily processable form, classifying information by its properties, preprocessing the information, 
etc. The subfield of AI precisely called KR especially studies computational models, languages 
and systems able to represent knowledge in an explicit way and to do inferences, or reasoning, 
on this knowledge.

Even if there have been heated debates about KR in the past, in particular with respect to 
the role of logic in KR, there is nowadays an agreement on some important properties of a KR 
language, namely: to be logically founded, to allow for a structured representation of knowledge, 
to have good computational properties, and to allow users to have a maximal understanding and 
control over each step of the knowledge base cycle.

The first point concerns the fact that the language is translatable into a logic: the expressions 
should be translatable into sentences of a given logic, and inferences in that language should 
correspond to deduction in this logic. In other words, the inference mechanisms should be logically 
sound (i.e., every piece of knowledge inferred is deducible in the target logical fragment) and 
complete (any piece of knowledge that cannot be inferred cannot be deduced either in the target 
logical fragment). This allows to give a precise semantics to expressions and inferences, and to 
compare different languages from an expressiveness viewpoint.

Knowledge structuring means that semantically related pieces of knowledge should be grouped 
together, and that different kinds of knowledge (such as facts, rules, constraints, goals etc.) should
be represented by different knowledge constructs. This can be motivated by model adequacy (i.e., its conformity to the modeling of the application domain) and by computational efficiency concerns. A large part of KR research can be seen as the search of good tradeoffs between the expressivity of a representation formalism and the computational complexity of the associated reasoning.

**Knowledge-based Systems.** Knowledge-based systems (KBS) are systems, built upon models, able to represent knowledge in an explicit way and do reasoning with. These systems include a knowledge base (KB), composed of different kinds of knowledge, and a reasoning engine. The reasoning engine processes knowledge in the KB to answer a question or to reach a certain goal (for instance to check the consistency of the KB or to build a sequence of actions in order to achieve a goal). The cornerstone of the knowledge base is the ontology. From an epistemological viewpoint, an ontology answers the question “what kinds of things exist in the application domain?” We consider here computational ontologies, which provide a symbolic representation of classes of objects, called concepts, as well as the possible relationships between objects, called relations or roles. All other pieces of knowledge in the KB are expressed by structures built with the ontology terms (concepts and relations).

Classically, in the building of a knowledge-based system, the first phase consists of knowledge elicitation: obtaining a system specification expressed in a language understandable by human beings, so that it can be checked by domain experts. This mediating representation does not need to be precise, consistent, or complete. Its role is to allow the experts to freely explicit knowledge and to communicate with others. The second phase consists of translating (the largest possible part of) this informal representation into a formal representation, expressed in a formal language provided with reasoning mechanisms, so that it can be checked whether this representation is consistent and complete with respect to the task to be solved. A major difficulty of this way of doing is ensuring the faithfulness of the formal representation with respect to the mediating representation. Checking faithfulness needs a validation and a revision cycle which is usually long: while the expert understands the mediating representation, this representation cannot be checked, and he/she does not understand the formal representation provided with the reasoning tools. One of the solutions proposed in (Shaw and Gaines (1995); Boe et al. (1997)) is to create mediating representations that are formal: expressing the representation in a language which is both understandable by human beings and formal and in this way ensuring expert simulation at an early modeling stage. This is precisely the qualities claimed by our graph-based language detailed in Section 2.

However, for a KBS to be really used in practice, an essential point is that the user understands and controls the whole process whose main steps are not only building a knowledge base and running the KBS (as previously discussed) but also obtaining results. By user, we either mean an end-user, who may be a knowledge engineer, who builds the KB, or an expert of the application domain, who uses the implemented representation to check its conformity with her own representation of the domain, or a user for whom the system has been built and who wants to solve real problems. It should be easy for this user not only to enter different pieces of knowledge and to understand their meaning but also to understand the results of the system and how the system computed these results. The last point, namely the ability of understanding why the system gives a certain answer, is especially important since the user computing expertise may vary. Furthermore, for any domain and level of expertise, explaining to the user each step that makes up the logical inference, generally remains a difficult process.
A Graph-based Language. In this paper, by “graph” we understand the classical mathematical notion in graph theory, i.e., a structure that consists of a set of nodes (also called vertices) and a set of edges that establish relationships (connections) between nodes. Please note that, regretfully, “graph” in elementary mathematics also refers to a function graph, i.e., a plot.

In the proposed graph-based approach, where all pieces of knowledge are represented by labeled graphs, the same language is used at all levels and for all KBS functionalities. The benefits of using graphs for representing knowledge at all levels of the KBS stem from the following:

- Firstly, graphs are simple mathematical objects (they only use elementary naive set theory notions such as elements, sets and relations) which have graphical representations (a set of points and lines connecting some pairs of points) and thus can be visualized.
- Secondly, there is a rich collection of efficient algorithms for processing graphs, thus graphs can be used as effective computational objects (they are widely used, for instance, in Operational Research).
- Thirdly, graphs can be equipped with a logical semantics: the graph-based mechanisms they are provided with are sound and complete with respect to deduction in the assigned logic.

Furthermore, graph-based mechanisms can be explained to the user because they can be easily visualized on the graphs themselves, either as a sequence of very simple operations or as a “global” operation. This point will be further detailed in Section 3.

Semantic Networks. In general, KR languages rely on a purely textual representation with strict syntactic and semantic rules. Domain concepts, their properties, relations and restrictions, are all represented by words and sentences of the representation language. Textual communication is often supplemented with visual properties (such as character types, styles, structure, or layout), but a knowledge representation language can be regarded as visual only if it is based on a pictorial expression. The human short term memory is limited, but visual organizations enable brain sensory information storage and ability to break down complex structures into more easily manageable chunks. Due to their visual qualities, semantic networks, which were originally developed as cognitive models, have been used for knowledge representation since the early days of Artificial Intelligence, especially in natural language processing.

The term semantic network encompasses an entire family of graph-based visual representations. Since Nude (Richens (1956)) and the semantic network T (Masterman (1962)), which concern natural language processing, many semantic networks systems have been introduced (cf. Lehman (1992) for a collection of papers concerning various families of network-based structures). They all share the basic idea of representing domain knowledge using a graph, but there are differences concerning notation, as well as rules or inferences supported by the language. In semantic networks, the diagrammatical reasoning is mainly based on path construction in the network. We can distinguish two major families of languages born in the eighties. Let us start with the KL-ONE family. In addition to the large number of systems implementing KL-ONE variants (Woods and Schmolze (1992)), KL-ONE is considered as the ancestor of Description Logics (DLs) (Baader et al. (2003)), which are nowadays the most prominent KR languages dedicated to reasoning on ontologies. However, Description Logics have lost their graphical origins. Secondly, Conceptual Graphs. They were introduced by Sowa (cf. Sowa (1976, 1984)) as a diagrammatic system of logic with the purpose “to express meaning in a form that is logically precise, humanly readable, and computationally tractable” (cf. Sowa (1984)). Throughout the remainder of this paper we use the term “Conceptual Graphs” to denote the family of formalisms rooted in Sowa’s work and then enriched and further developed with a graph-based approach (cf. Chein and Mugnier (2009)).
Paper Organization. The sequel of this paper is structured as follows. Section 2 presents
the main syntactic constructs of the language. Section 3 presents the elementary graph-
based reasoning mechanisms and explains how labeled graph homomorphism encompasses all
elementary operations in one global operation. Please note that, in this paper, we do not enter
into precise definitions and notations but rather rely on visual intuition (see Chein and Mugnier
(2009) for more details and technical developments). An application scenario is presented in
Section 4. We conclude the paper with Section 5 that presents related work in the domain and
lays down future work directions. All figures depict graphs drawn using the conceptual graph
editor Cogui\footnote{\url{http://www.lirmm.fr/cogui/}}. Please note that Cogui is also fully integrated with the conceptual graph engine
Cogitant\footnote{\url{http://cogitant.sourceforge.net/}} to perform reasoning on the above mentioned graphs.

2 Using graphs for representation: the good

In our approach, all kinds of knowledge are encoded as graphs and thus can be visualized in a
natural way:

- The vocabulary, which can be seen as a basic ontology, is composed of hierarchies of concepts
  and relations. These hierarchies can be visualized by their Hasse diagram, the usual way of
drawing a partial order (see Figures 1 and 2).
- All other kinds of knowledge are based on the representation of entities and their relationships.
  This representation is encoded by a labeled graph, with two kinds of nodes, respectively
corresponding to entities and relations. Edges link entity nodes to relation nodes. These
nodes are labeled by elements in the vocabulary (see Figure 3).

These graphs have a semantics in first-order logic (FOL), i.e., a knowledge base can be translated into a set of first-order logical formulas. Reasoning tasks operate directly on the
knowledge defined by the user and not on their translation into logical formulas. Stated in an other
way, the logical semantics is only used to formally ground the graph model, i.e., representation
and reasoning mechanisms. This makes it possible to explain reasoning to the end-user because
it can be visualized in a natural way on the pieces of knowledge he/she is familiar with. Would a
logical prover be used on the logical translation of these pieces of knowledge to compute reasoning,
reasoning would become a black box for the user and could not be explained.

2.1 Conceptual vocabulary

The vocabulary is composed of two partially ordered sets: a set of concepts and a set of relations
of any arity (the arity is the number of arguments of the relation). The partial order represents
a specialization relation: \( t' \leq t \) is read as “\( t' \) is a specialization of \( t \). If \( t \) and \( t' \) are concepts,
\( t' \leq t \) means that “every instance of the concept \( t' \) is also an instance of the concept \( t \). If \( t \) and
\( t' \) are relations, then these relations have the same arity, say \( k \), and \( t' \leq t \) means that “if \( t' \) holds
between \( k \) entities, then \( t \) also holds between these \( k \) entities”). Figures 1 and 2 shows parts of
these hierarchies visualized by their Hasse diagram (\( t' \leq t \) if there is a path from \( t' \) up to \( t \)). For
instance, the concept TeddyBear is a specialization of the concept Object, because of the path
(TeddyBear, Toy, Object); the relation siblingOf is a specialization of the relation link_2
(\( k \) stands for any binary relation) because of the path (siblingOf, relativeOf, link_2). Note that a
hierarchy is not necessarily a tree: for instance, there are two paths from Woman to Person,
namely (Woman, Female, Person) and (Woman, Adult, Person).

Names of specific individuals can also be included in the vocabulary. The vocabulary can be
further enriched by signatures for relations indicating the maximal concept that can be assigned
to each of the relation arguments (e.g. the first argument of the relation motherOf is of maximal
type Woman and its second argument is of maximal type Person). It can also contain statements
of disjointness between concepts (e.g. the two types Object and Person are disjoint).
2.2 Basic graphs

A basic conceptual graph (BG) is a bipartite graph: one class of nodes, called concept nodes, represents entities and the other, called relation nodes, represents relationships between these entities or properties of them. E.g., the BG in Figure 3 graphically represents the following situation: “The boy John is a sibling of the girl Eva. John is giving a sweet to Eva, who is holding a red teddy bear belonging to John.”

A concept node is labeled by a couple $t:m$ where $t$ is a concept (and more generally, a list of concepts) called the type of the node, and $m$ is called the marker of this node: this marker is either the generic marker, denoted by $\ast$, if the node refers to an unspecified entity, otherwise this marker is a specific individual name. E.g., in Figure 3 the node $[\text{Sweet}:\ast]$ refers to “a” sweet, while the node $[\text{Boy:John}]$ refers to “the” boy John. A relation node is labeled by a relation $r$ called its type, and, if $k$ is the arity of $r$, this node is incidental to $k$ totally ordered edges. E.g., in Figure 3 the relation node of ternary type $\text{give}$ has three incidental edges and the order on these edges allows to distinguish between the agent of the gift act $[\text{Boy:John}]$, its recipient $[\text{Girl:Eva}]$ and its object $[\text{Sweet}:\ast]$. Classically, concept nodes are drawn as rectangles and relation nodes as ovals and the order on edges incidental to a $k$-ary relation node are numbered from 1 to $k$.

BGs are used to represent assertions called facts. They are also building blocks for more complex kinds of knowledge, as outlined in the next section.
2.3 More complex graphs

In the following we present two examples of basic conceptual graph extensions: nested graphs, which allow to structure facts by level of detail; and inference rules, which enrich the basic ontology with general knowledge about a domain.

**Nested graphs.** In a nested graph, a concept node may itself contain a (nested) graph, whose role is to further describe the entity represented by the node. This allows to distinguish between internal and external information about an object, to represent zooming into an object or to contextualize the description of an object. For instance, let us consider the nested graph in Figure 4. At the outermost level, this graph says that “Eva is giving a picture that she did to John” (note however that time is not represented here) and the graph nested in the node referring to the picture further describes this picture: “this picture shows a boy holding a teddy bear”. The dotted line is a coreference link; it links two nodes that refer to the same entity (in this example the boy called John). The information that the picture has been done by Eva can be seen as an external information about the picture, while the detail of what is in the picture can be seen as an internal information, that can be obtained by zooming into the picture. It can also be said that the piece of information nested in a node is relevant within the context represented by this node (here, John is holding a teddy bear in the context of the picture, but it may not be true in the outermost context).
Rules. A rule expresses implicit knowledge of the form “if hypothesis then conclusion”, where hypothesis and conclusion are both basic graphs. This knowledge can be made explicit by applying the rule to a specific fact: intuitively, when the hypothesis graph is found in a fact, then the conclusion graph can be added to this fact (see Sect. 3.4 for more details). There is a one to one correspondence between some concept nodes in the hypothesis with concept nodes in the conclusion. Two nodes in correspondence refer to the same entity. These nodes are said to be connection nodes. For instance, Figures 5 and 6 present two rules, with the hypothesis on the left hand side and the conclusion on the right, separated by a vertical line. In Figure 5, rule $R_1$ says that “if a person is a sibling of a person, then the inverse relation holds between these persons”. More formally: “for all persons $x$ and $y$, if $x$ is a sibling of $y$ then $y$ is a sibling of $x$” (all concept nodes are connection nodes). In Figure 6, rule $R_2$ says that “for all persons $x$ and $y$, if $x$ is a sibling of $y$, then they have a common parent, i.e., there is a person who is a parent of $x$ and of $y$” (the node representing this person is not a connection node, since it is not in correspondence with a node in the hypothesis). Let us add that rules can also be defined as pairs of nested graphs instead of basic graphs.

Figure 5 A rule ($R_1$)

Figure 6 Another rule ($R_2$)

All these graphical objects, i.e., the vocabulary as well as basic graphs, nested graphs and rules, are provided with a semantics in first-order logic. This semantics specifies the meaning of knowledge constructs and allows to show the correctness of the associated graph mechanisms with respect to logical deduction (see Sect. 3.3).
3 Using graphs for reasoning: the better

Different kinds of reasoning concerning BGs can be graphically defined, e.g., applying inference rules or contextual reasoning. These reasonings are based on a subsumption relation between conceptual graphs. This section is devoted to the presentation of this fundamental reasoning notion in the simplest case, i.e., BGs.

Let $G$ and $H$ be two BGs over the same vocabulary. Intuitively, $G$ subsumes $H$ if the fact—or the information—represented by $H$ entails the fact represented by $G$, or in other words, if all information contained in $G$ is also contained in $H$.

A query-answering mechanism using BGs and subsumption can be defined as follows. Let us consider a knowledge base $B$ composed of a set of BGs, representing some assertions about a modeled world, e.g., the fact in Figure 3. Elements in $B$ answering a query $Q$ are intuitively defined as the elements that entail $Q$, or equivalently, elements that are specializations of $Q$, or also, elements that are subsumed by $Q$. Let us consider for instance the query in Figure 7.

This query is easily visualized as a graph, but is more complex to express textually: it asks for a situation where a boy and a girl, who is one of the boy’s relatives, are each in relation with a red toy. We will see hereafter why and how the fact in Figure 3 answers this query.

Figure 7 A query described by a basic graph ($G$)

Relationships with logics is mentioned at the end of this section and we will see that the subsumption relation exactly corresponds to deduction in a fragment of first-order logic. The subsumption relation can be defined either by a sequence of elementary operations or by the classical homomorphism notion applied to BGs. Both are very easily visualizable and they are defined below by means of drawings.

3.1 Generalization and Specialization Operations

There are five elementary generalization operations and five inverse operations, called elementary specialization operations. The terms generalization and specialization are used here with the following intuitive meaning: let $I$ be a piece of information; whenever a piece of information is added to $I$ the obtained information is a specialization of $I$ (it contains more specific knowledge) and, conversely, deleting a piece of information from $I$ yields a final piece of information that is more general than $I$ (it contains less precise knowledge).

3.1.1 Elementary Generalization Operations for BGs

Any generalization operation is a “unary” operation, i.e., it transforms a BG into another BG. It can be pictured by a drawing representing the transition from the input BG to the output BG. Generalization has to be taken in a broad sense, i.e., the BG obtained may contain a strictly more general information than the initial BG or the same information.
The elementary generalization operations can be graphically defined as follows.

- **Substract** (Figure 8). The Substract operation consists of deleting some connected components of a BG. The BG obtained is clearly more general than (or equivalent to) the original BG, since a piece of information is deleted.

- **Detach** (Figure 9). The Detach operation consists of splitting a concept node \( c \) into two concept nodes \( c_1 \) and \( c_2 \), the edges incident to \( c \) being shared between \( c_1 \) and \( c_2 \). For instance, let us consider the detachment of the generic concept node \( c \) in Figure 9. In the initial BG it is said that “there is a boy who possesses something and is giving something to a person”, and in the resulting BG it is said that “there is a boy who possesses something and there is a boy giving something to a person”. In the resulting BG, the two boys may be different, while in the initial BG it is necessarily the same boy. Therefore, the final situation is more general than the initial situation.

- **Increase** (Figure 10). The Increase operation consists of increasing the label of a concept or relation node. In the case of a concept node, it means that one can increase its type, e.g., replacing “the girl Eva” by “the person Eva” and/or replace an individual marker by the generic marker, e.g., transforming “the person Eva” into “a person”. Formally, the generic marker is considered as greater than all individual markers, which are pairwise non-comparable. Thus, increasing a concept node label consists of increasing its type and/or its marker. Clearly, “a person” is more general (in an intuitive sense) than “the girl Eva”. In the same way, replacing a relation type by a greater type is also clearly a generalization operation, e.g., “John is a relative of Eva” is more general than “John is a sibling of Eva.”

Let us remark that checking if a type \( t \) is greater than another type \( t' \) is the most frequent operation in hierarchies. It is a basic operation (\( t \) is greater than \( t' \) if and only if there is a path from \( t' \) to \( t \)) for which efficient algorithms have been developed (cf. Chein and Mugnier (2009)). In Figure 11, the bold paths contain all types greater than the type Boy.

- **Relation duplicate** (Figure 12). The Relation duplicate operation consists of duplicating a relation node, i.e., adding a new relation node \( r' \) having the same type and the same list of arguments as a relation node \( r \). \( r \) and \( r' \) are said to be twin relation nodes.

- **Copy** (Figure 13). The Copy operation consists of duplicating a whole BG, i.e., adding to it an isomorphic and disjoint copy of it.

![Figure 8 Substract](image-url)
In the last two operations the structure of the obtained BG contains the structure of the initial BG (one adds something), thus, at first glance, one can think that they are specialization operations. Nevertheless, as these operations duplicate already existing information, the BG obtained is semantically equivalent to the initial one, thus they are also generalization operations (in a broad sense).

We can now precisely define what “G is a generalization of H” means: G is a generalization of H if there is a sequence of elementary generalization operations leading from H to G, i.e., there is a sequence of BGs \( H_0 = (H), H_1, \ldots, H_n = (G) \), such that for all \( i = 1, \ldots, n \), \( H_i \) is obtained from \( H_{i-1} \) by an elementary generalization operation.

Figures 14, 15, 16, 17, 18, present some of the graphs occurring in a generalization sequence from \( H \), the BG in Figure 3 to \( G \), the BG in Figure 7. \( H_1 \) is obtained from \( H \) by splitting both nodes [Girl:Eva] and [Boy: John] (two Detach operations). \( H_2 \) is obtained from \( H_1 \) by deleting the connected component containing the give relation node (Subtract operation). \( H_3 \) is obtained from \( H_2 \) by duplicating the relation node color (Relation duplicate operation). \( H_4 \) is obtained from \( H_3 \) by a Detach operation on the node [TeddyBear:*]. \( G \) is obtained from \( H_4 \) by a sequence of seven Increase operations: the relation siblingOf is replaced by relativeOf; the
relations *possess* and *hold* are replaced by *link2*; the individual concept nodes [Boy:John] and [Girl:Eva] are made generic, and the teddy bears become toys.
Figure 15 Generalization from $H$ to $G$ - step II ($H_2$)

Figure 16 Generalization from $H$ to $G$ - step III ($H_3$)

Figure 17 Generalization from $H$ to $G$ - step IV ($H_4$)
3.1.2 Elementary Specialization Operations

We have seen in the previous section that the elementary generalization operations are indeed generalization operations in an intuitive manner, they are easy to draw and to understand, and they allow for a precise definition of the subsumption relation between BGs. Nevertheless, let us consider again the query-answering problem previously stated using generalization. Let $Q$ be a BG query and $B$ a set of BG facts. Answering $Q$ consists of looking for subgraphs of BGs in $B$ that are subsumed by $Q$, i.e., such that $Q$ generalizes them. It seems more intuitive and it is more efficient to start from the query $Q$ and to look for specializations of $Q$ in $B$. This can be done by defining elementary specialization operations which are the inverse of the elementary generalization operations defined previously.

- **Disjoint sum** (Figure 19). Given two disjoint BGs, their Disjoint sum is the BG obtained by juxtaposing two copies of these BGs. This operation is the inverse of the **Substract** operation.
- **Join** (Figure 20). Given a BG, joining two concept nodes with the same label in this BG consists of merging them. This operation is the inverse of the **Detach** operation.
- **Restrict** (Figure 21). **Restrict** consists of decreasing the label of a concept or relation node. This operation is the inverse of the **Increase** operation.
- **Relation simplify** (Figure 22). This operation consists of deleting a twin relation node. This operation is the inverse of the **Relation duplicate** operation.
- **Copy**. This operation has already been defined as a generalization operation.

![Figure 19 Disjoint sum](image-url)
$H$ is a specialization of $G$ if $H$ can be obtained from $G$ by a sequence of elementary specialization operations. In reading Figures 14, 15, 16, 17, 18 backwards, one obtains a specialization sequence from $G$ to $H$. This sequence begins with a set of Restrict operations (leading from $G$ to $H_4$). Then, $H_3$ is obtained from $H_4$ by a Join operation. $H_2$ is obtained from $H_3$ by Relation Simplify. $H_1$ is obtained from $H_2$ by a Disjoint sum operation, and $H$ is obtained from $H_1$ by two Join operations.

The following property is straightforward to check:

$G$ is a generalization of $H$ if and only if $H$ is a specialization of $G$. 

---

Figure 20  Join

Figure 21  Restrict

Figure 22  Simplify
3.2 Homomorphism

We have seen specialization operations, which are more convenient than generalization operations when considering the query-answering problem. Now, the problem is how to find a sequence of specialization operations from a BG to another BG.

In this section, we introduce the homomorphism notion between BGs. A homomorphism from $G$ to $H$ is a mapping from the node set of $G$ to the node set of $H$, which preserves the adjacency between nodes of $G$ and can decrease the node labels. If there is a homomorphism (say $\pi$) from $G$ to $H$, we say that $G$ maps to $H$ (by $\pi$).

Let us consider again the query $G$ in Figure 7 and the fact $H$ in Figure 3. There is a homomorphism from $G$ to $H$ which is pictured by the dashed lines in Figure 23. The concept node $a = [\text{Boy} : \ast]$ in $G$ is mapped to $[\text{Boy} : \text{John}]$ in $H$, the concept node $b = [\text{Girl} : \ast]$ in $G$ is mapped to $[\text{Girl} : \text{Eva}]$ in $H$, both concept nodes $c = [\text{Toy} : \ast]$ and $d = [\text{Toy} : \ast]$ in $G$ are mapped to the same node $[\text{TeddyBear} : \ast]$ in $H$, the concept node $e = [\text{Color} : \text{Red}]$ in $G$ is mapped to $[\text{Color} : \text{Red}]$ in $H$, the relation node (relativeOf) is mapped to the relation node (siblingOf), the relation node (link2) from $a$ to $c$ is mapped to the relation node (possess) and the other relation node (link2) from $b$ to $d$ is mapped to the relation node (hold); finally, both relation nodes (color) are mapped to the same node (color).

A BG homomorphism can be more precisely defined as follows. A homomorphism $\pi$ from $G$ to $H$ is a mapping from the concept node set of $G$ to the concept node set of $H$ and from the relation node set of $G$ to the relation node set of $H$, which preserves edges and may decrease concept and relation labels, that is:

- for any edge labeled $i$ between nodes $c$ and $r$ in $G$, there is an edge labeled $i$ between nodes $\pi(c)$ and $\pi(r)$ in $H$; in other words, if a relation $r$ has neighbors $c_1 \ldots c_k$ (in this order) then its image $\pi(r)$ has neighbors $\pi(c_1) \ldots \pi(c_k)$ (in this order).
- for any (concept or relation) node $x$ in $G$, the label of its image $\pi(x)$ in $H$ is less than or equal to the label of $x$.

Let us consider again the homomorphism in Figure 23. Figure 24 highlights the subgraph of $H$ induced by the nodes which are images of nodes in $G$. This subgraph is called the “image graph” of $G$ by this homomorphism.
The following theorem holds. Given two BGs $G$ and $H$, the three following propositions are equivalent:

1. $G$ is a generalization of $H$
2. $H$ is a specialization of $G$
3. There is a homomorphism from $G$ to $H$

Even though it is easy to visualize a homomorphism and to check if a mapping between two BGs is a homomorphism (cf. Figure 23), this global graph matching can be replaced, if needed, for more detailed explanation purposes, by a sequence of elementary operations (cf. Figures 14 to 18). Assume for instance that the answer to the query $G$ is visualized as in Figure 24 and the user wants to understand why the image graph of $G$ is indeed a specialization of $G$. The homomorphism can be decomposed into a sequence of elementary specialization operations, starting from $G$, as follows:

- Firstly, a sequence of Restrict showing how the label of each node of $G$ is specialized (cf. the transformation from $G$ to $H_4$);
- Secondly, a sequence of Join showing which concept nodes are merged into the same node (these are the nodes in $G$ with the same image by the homomorphism, cf. the transformation from $H_1$ to $H_3$);
- Thirdly, a sequence of Relation simplify removing relation nodes that have become redundant (cf. the transformation from $H_3$ to $H_2$).

After these three steps, the image graph of $G$ is obtained, which is sufficient to show that the fact contains a specialization of $G$. To build the fact graph itself from the image graph of $G$, one would need a disjoint sum (cf. the transformation from $H_2$ to $H_1$) and some joins (cf. the transformation from $H_1$ to $H$).

3.3 Logical correctness

Until now, we have introduced the reasoning operations (generalization, specialization and subsumption) using simple graphical operations. It remains to relate these notions to usual reasoning notions, i.e., essentially, to relate BG subsumption to logical deduction. This can be done using the logical semantics of the knowledge constructs. This semantics is defined by a mapping from graphical objects to logical formulas. It is classically denoted by $\Phi$ in conceptual graphs (Sowa (1984)). The fundamental theorem states that given two BGs $G$ and $H$ built on a vocabulary $V$, there is a homomorphism from $G$ to $H$ if and only if $\Phi(G)$ is a semantic consequence of $\Phi(H)$ and $\Phi(V)$ (this is a soundness and completeness theorem of BG homomorphism w.r.t. FOL entailment, cf. Chein and Mugnier (1992)). Let us point out that BGs are in fact equivalent to the positive, conjunctive and existential fragment of FOL.

Once again, logic is used to give a semantics to BGs, but not to reason with them. As detailed before, one motivation for preferring graph-based reasoning is its visual aspects permitting to understand (logically based) reasoning without doing logic. Another motivation is that BGs have...
good computational properties. Efficient graph-based deduction algorithms have been built, which are not the translations of logical procedures (see f.i. Chein and Mugnier (2009)).

### 3.4 Overview of reasoning on more complex pieces of knowledge

Previous generalization and specialization elementary operations, as well as the corresponding homomorphism notion, can be extended to nested graphs, while preserving soundness and completeness with respect to deduction in the associated fragment of FOL.

Let us now consider the graph rules presented in Section 2. A rule $R$ can be applied to a BG $H$ if there is a homomorphism from its hypothesis to $H$. Applying $R$ to $H$ according to such a homomorphism $\pi$ consists of “attaching” to $H$ the conclusion of $R$ by merging each connection node in the conclusion with the image by $\pi$ of the corresponding connection node in the hypothesis. See for instance the graph $H$ in Figure 3 and the rules $R_1$ and $R_2$ in Figures 5 and 6. There is a homomorphism from the hypothesis of $R_1$ to $H$, thus $R_1$ can be applied to $H$, which yields the graph $K$ (Figure 25). Similarly, $R_2$ can be applied to $H$, or to $K$. Let us apply $R_2$ to $K$: we obtain $L$ (Figure 25). $R_2$ can be applied another time with a new homomorphism to $L$; however, this application would be redundant, since the part to be added is already present in $L$.

![Figure 25 Applying rules](image)

When a knowledge base contains a set of facts and a set of rules, the query mechanism has to take implicit knowledge coded in rules into account. The knowledge base answers a query $Q$ if a BG $F'$ can be derived from the facts using the rules, such that $Q$ maps to $F'$. Let us consider again the fact $H$ in Figure 3 and the rules $R_1$ and $R_2$ in Figures 5 and 6 and let $Q$ be the query in Figure 26 asking if there is someone who is parent of a boy and a girl: there is no homomorphism from $Q$ to $H$; however, the knowledge base containing $H$ and the rules $R_1$ and $R_2$ answers $Q$: indeed $Q$ maps to $L$ (Figure 25), which is derived from $H$ by applying the rules. This reasoning can be explained by visualizing a homomorphism from $Q$ to $L$, as well as a sequence of rule applications allowing to add the knowledge involved in this homomorphism (for instance, the application of $R_1$ is not needed in our example).

Finally, let us point out that this rule application mechanism is sound and complete, i.e., given a KB $K$ and a BG $Q$, $Q$ maps to a graph derived from $K$ if and only if $\Phi(K) \models \Phi(Q)$, where $\Phi(K)$ is the set of formulas assigned to the vocabulary, the set of facts and the set of rules composing $K$. 
Using graphs for applications: the best

In this section we present a concrete Artificial Intelligence application using the above described language for image annotation. The choice of the application is motivated twofold. Firstly, this application clearly demonstrate the visual appeal of Conceptual Graphs from a representation depiction faithfulness viewpoint. Secondly, the visual reasoning capabilities allow for all levels of expertise when building, querying the knowledge base and understanding why certain results will be returned.

Within the image annotation process we will distinguish between resources (in this case electronic image files) and metadata. A metadata is a computational object always associated with a resource. Each resource is identified by an identifier, which is used in the metadata base for referencing the resource.

Metadata can be roughly categorized into two classes: objective metadata and subjective metadata. Examples of objective metadata include: resource address, authors name and the document size. Subjective metadata aims at representing information generally depending on the author of the metadata. Examples of subjective metadata include: the representation of the content of a resource (indexation of the resource), the representation of a comment, note, or remark etc. In this case an annotation is simply a piece of knowledge associated with a resource.

In the following, we will present a Conceptual Graph approach for building and querying a knowledge base aimed at annotating family photos. The knowledge base used to illustrate notions throughout this section has been edited with the tool Cogui.

Such annotation is built from an ontology fundamentally composed of a hierarchy of concepts (or terms) and a hierarchy of relations between concepts. The ontology can also contain representations of other knowledge. Relation signatures indicate the types of relation arguments. Rules represent knowledge of the form “if a piece of information is present (within an annotation) then further information can be added (to this annotation)”. Thus, rules can be used to automatically complete an annotation by implicit and general knowledge. Another kind of knowledge with the same syntactic form as rules but a different semantics are constraints. Constraints represent knowledge of the form “if a piece of information is present (within an annotation) then other information cannot be present (in the annotation)”. Signatures and constraints are used to avoid the construction of absurd annotations. All these kinds of knowledge are represented by labeled graphs.

For clarity purposes the example given in this paper is very simple. This framework have been successfully employed for annotation in the large scale context of the LOGOS Framework 6 European Project (cf. for instance, Lalande et al. (2009)), as well as in other French projects (Moreau et al. (2007), Genest and Chein (2005)).

Let us consider the photograph in Figure 27. A semantic annotation of this image is depicted in Figure 28 where a fact represents a girl, the relative of a child, playing with the same red train that the child is playing with. As explained above, all of the concepts and the relations used in
the facts need to be described and organized in the vocabulary. Figure 29 shows the concept and relation hierarchies purposely built for annotating family images.

Figure 27 Example of photo that needs to be semantically annotated

Figure 28 Example of a semantic annotation
Figure 29  Concept / Relation hierarchy for photo annotation

Please note that the constructs introduced before (such as rules and nested graphs) are also used for annotation. Since certain chunks of knowledge appear often, other kinds of constructs have been introduced specifically for speeding up the annotation process, such as prototype graphs.

For example, for a child we could always like to have annotated the fact that it is playing with a certain object. Notice this is not a rule, e.g., it may apply in certain situation and not in others. Figure 30 represents how to insert the prototypical graph for a given concept.

As shown before, the user can then look for certain photos that contain a child and its relative, a girl, both acting with a toy. Such query is visually represented in Figure 31. Based on homomorphism (as previously explained) the query can be “mapped” into the fact represented in Figure 28 and this will return the photo attached to it.

Note that we have only presented here the kernel of an information retrieval system, in which the search process is based on graph homomorphism. In order to take the intrinsic vagueness of information retrieval into account, i.e., to search documents imprecisely and incompletely represented in order to answer a vague query, the exact search realized by graph homomorphism is not sufficient. Additional techniques based on graph transformations for doing approximate search and for ranking the answers to a query have been developed (cf. for instance Genest and Chein (2005)).

5 Related work and conclusion

In this section, we place our language in the landscape of graphical knowledge representation languages in order to enhance its original features. We will only detail each language in the light of its respective distinction with Conceptual Graphs. This choice is motivated by our aim of demonstrating the originality of our proposal in the context of graph-based languages for both knowledge representation and reasoning as opposed of doing a general synthesis of existing languages for KR.

An important criterium distinguishing Conceptual Graphs from other graph-based languages for knowledge modeling is the reasoning aspect. Indeed, numerous graphical languages have been proposed for data and knowledge modeling. Prominently amongst them, UML (Unified Modeling Language) unifies several previous languages and allows to model a system or a program by diagrams. However, this language does not have a denotational semantics and is not provided with inference mechanisms.

Furthermore, let us focus solely on graphical languages fundamentally dedicated to representing knowledge in the form of relationships between concepts and/or concept instances. The name “map” is often used to describe mediating, thus informal, representations. A concept map is a diagram representing relationships between concepts, or more vaguely, ideas, images, words, etc., the aim being to organize informal knowledge (Novak and Canas (2006)). A cognitive map is a graphical representation of an influence network between notions. A topic map is a diagram representing associations between topics, and is more specifically dedicated to the description of resources for the Semantic Web. If all these languages provide graphical views of knowledge, none of them possesses a formally based reasoning mechanism.

Closer to our proposal, let us cite RDF (Resource Description Framework), which is the basic Semantic Web language. RDF has a graph-based representation, it is provided with a formal semantics and an associated entailment notion (Hayes (2004), Horst (2004)), but it does not come with an effective reasoning mechanism, even less with a graph-based mechanism that would operate on the graph representation.

Let us point out that for several of these languages, some form of formally founded visual reasoning based on graph homomorphism has been proposed: Raimbault et al. (2005); Chauvin et al. (2008); Aissaoui et al. (2003); Carloni et al. (2006); Baget (2005).

We have already mentioned in Section 1 the semantic network family, and its successors, description logics, which are logically founded knowledge representation and reasoning languages, which have lost their diagrammatical aspects. In contrast, the Semantic Network Processing System (SNePS) (see Shapiro (1979, 2000)), specially dedicated to the implementation of cognitive agents, remains graph-based. It is provided with three kinds of inference mechanisms: a sound (but not complete) logic-based inference, as well as a path-based inference and a frame-based inference. All three kinds of inferences can be integrated, but there is no formal semantics for this combination.

Conceptual Graphs finally appears to be the only knowledge representation language both logic-based and graph-based, with logically sound and complete graph inference mechanisms (at least for the fragment developed here), thus allowing for visual reasoning. Another important feature of conceptual graphs is that relations can be of any arity (i.e., they can have any number of arguments), which allows for a more natural representation in many cases (for instance, when relations are extracted from data tables, their arity is the number of columns in the table). This latter feature is shared with topic maps, but none of the other languages mentioned above.

The sound and complete graph-based mechanisms for reasoning presented in this paper have been fully implemented and are available as part of the Cogui Editor and the CG reasoning engine Cogitant. While homomorphism proves to be an intuitive mechanism for query answering, more advanced graph-based tools could be envisaged to make this notion even more intuitive (see for

3http://www.w3.org/TR/REC-rdf-syntax/
example the 3D manipulation of the images in Figure 23). This is not the only possible envisaged manipulation: different layouts, smooth zooming capabilities or colors could also be employed to increase the presentive qualities of our language.

Distinguishing Answers in Conceptual Graph Knowledge Bases

Abstract. In knowledge bases (KB), the open world assumption and the ability to express variables may lead to an answer redundancy problem. This problem occurs when the returned answers are comparable. In this paper, we define a framework to distinguish amongst answers. Our method is based on adding contextual knowledge extracted from the KB. The construction of such descriptions allows clarification of the notion of redundancy between answers, based not only on the images of the requested pattern but also on the whole KB. We propose a definition for the set of answers to be computed from a query, which ensures both properties of non-redundancy and completeness. While all answers of this set can be distinguished from others with a description, an open question remains concerning what is a good description to return to an end-user. We introduce the notion of smart answer and give an algorithm that computes a set of smart answers based on a vertex neighborhood distance.

1 Motivation

In the semantic web age, a large number of applications strongly rely on the building and processing of knowledge bases (KB) for different domains (multimedia, information management, semantic portals, e-learning, etc.). The formal languages used for representation will encounter obvious scaling problems and therefore rely on implicit or explicit graph based representations (see for example Topic Maps, RDF, Conceptual Graphs, etc.) As a direct consequence, querying such systems will have to be done through graph based mechanisms and, accordingly, optimization techniques implemented [1].

In ICCS’08 [2], we identified the semantic database context in which a set of answers has to be computed. For this case, there are two kinds of answer graphs: answers as subgraphs of the knowledge base graph that are used for browsing the KB or for applying rules; and answers as graphs, independent of the KB, corresponding to the classical use of a querying system. With this latter kind

\[^1\]

For example, in SPARQL, as blank node labels can be renamed in results, see [1] ¶ 2.4.
of answer, an important problem concerns detecting redundant answers. Unlike
classical databases, redundancies are not limited to duplicate tuples. Indeed, the
presence of unspecified entities (generic markers in CG or blank nodes in RDF)
and also a type hierarchy leads us to consider that an answer which is more
general than another as redundant. In [2], we studied this problem and proposed
to return irredundant forms of the most specific answers to a query.

An important problem arising in this context is ultimately related to the
nature of a KB vs. a database. With a classical database, one can assume that
a query designer knows the database schema and is thus able to build a query
accordingly to its needs. With a KB, the schema is extended to an ontology
and the different assertions are not supposed to instantiate a specific frame (the
knowledge is semi-structured). Consequently, it is difficult for a query designer
to specify the content of the searched knowledge: he/she wants to obtain some
information about a specific pattern of knowledge. The suppression of redundant
answers only by comparing answer graphs independently of the KB results in the
problem not being considered. A better way to address the redundancy problem
consists of completing the answer graphs with their neighborhood to obtain more
detailed answers in order to return some relevant knowledge to the end-user in
order to get insight (restitution, reflet) into the diversity of the knowledge in the
KB. Moreover, users seem to prefer answers in their context (e.g. paragraph)
rather than the exact answer[3].

In this paper we focus on answers given in a graph based form. Our motivation
stems from the homogeneity of preserving the same format between the KB,
query and answer. Moreover, this will allow the reuse of answers as a KB for
different future answers (see for example nested queries). Note that while this
paper focuses solely on the problem of distinguishing graph based answers, the
same research problem will arise and results will be obtained when of answers
are represented as a tuple.

2 Contribution and related work

Figure 1 shows a query, a conceptual graph formalized KB (see section 3.1) and
all five answers to the query in the KB (from A₁ to A₅, in gray in the picture).

The problem that arises in this scenario is how to define relevant answers
when they are independent of the KB (i.e. a set of answer graphics and not a set
of answer subgraphs of the KB). For instance, answers A₁ and A₅ are equivalent
(“there is a human who owns an animal”), and knowledge expressed by these
answers is expressed by all of the others. The open world assumption makes it
impossible to state that all humans or animals represent distinct elements of the
described world. Therefore it seems preferable to only return answers that bring
more knowledge, i.e. in our example that “Mary owns a cat” and “a human owns
a dog”. But another relevant answer could be that “there is a human knowing
Mary who owns a cat”.

The contribution of the paper is to refine our preceding notion of redundancy
between answers, to take the knowledge of the KB into account, through the
Fig. 1. Query, KB and highlighted answers.

notion of a fair extension of an answer, a graph that specifically describes an answer. Thus, an answer is irredudant if there is such a “fair” extension. A special case of this problem (when the answer is a concept node) corresponds to the problem of Generation of Referring Expressions (GRE) studied in the conceptual graph context in [4], that we extend for our purposes. Based on the extended notion of redundancy, we define two answer subset properties of non-redundancy (there is no redundant answer in the subset) and completeness (each answer is redundant to an answer of the subset). We then explain how to compute all the non-redundant and complete subsets of answers, based on a redundancy graph. We then discuss what is a good set of referring graphs to be returned to the user, and give an algorithm that fulfills these good properties.

As previously mentioned, a special case of answer identification was studied in [4]. The RDF query language SPARQL offers a way to describe answers (by the DESCRIBE primitive) but it does not address the specific problem of distinguishing one answer from another according to semantically sound syntactic criteria. The problem of answer redundancy in the Semantic Web context has been studied in [5], but the redundancy stated in this paper concerns the union of all answers, and corresponds, in the CG field, to the classical notion of ir-redundancy (see section 3.1), as opposed to our redundancy between answers. In an article about OWL-QL [6] the notion of server terseness is defined, which is the ability of a server to always produce a response collection that contains no redundant answers (i.e. there is no answer that subsumes another one). This corresponds to our previous notion of redundancy defined in [2].

In the next section, preliminary notions about conceptual graphs and our query framework are given. Section 4 deals with the extended notion of redundancy between answers and its application to a subset of answers. In section 5 we discuss the relevancy of the set of referring graphs returned to the user. We conclude our work in the last section.

3 Preliminary notions

3.1 Simple Graphs

The conceptual graph formalism we use in this paper has been developed at LIRMM over the last 15 years [7]. The main difference with respect to the initial
general model of Sowa [8] is that only representation primitives allowing graph-based reasoning are accepted.

Simple graphs (SGs) are built upon a support, which is a structure \( S = (T_C, T_R, I, \sigma) \), where \( T_C \) is the set of concept types, \( T_R \) is the set of relations with any arity (arity is the number of arguments of the relation), \( T_C \) and \( T_R \) are partially ordered sets. The partial order represents a specialization relation (\( t' \leq t \) is read as “\( t' \) is a specialization of \( t \)”). \( I \) is a set of individual markers. The mapping \( \sigma \) assigns a signature to each relation specifying its arity and the maximal type for each of its arguments.

SGs are labeled bipartite graphs denoted \( G = (C_G, R_G, E_G, l_G) \) where \( C_G \) and \( R_G \) are the concept and relation node sets respectively, \( E_G \) is the set of edges and \( l_G \) is the mapping that labels nodes and edges. Concept nodes are labeled by a couple \((t : m)\), where \( t \) is a concept type and \( m \) is a marker. If the node represents an unspecified entity, its marker is the generic marker, denoted \( * \), and the node is called a generic node, otherwise its marker is an element of \( I \), and the node is called an individual node. Relation nodes are labeled by a relation \( r \) and, if \( n \) is the arity of \( r \), it is incidental to \( n \) totally ordered edges.

A specialization/generalization relation corresponding to a deduction notion is defined over SGs and can be easily characterized by a graph homomorphism called projection. When there is a projection \( \pi \) from \( G \) to \( H \), \( H \) is considered to be more specialized than \( G \), denoted \( H \leq G \). More specifically, a projection \( \pi \) from \( G \) to \( H \) is a mapping from \( C_G \) to \( C_H \) and from \( R_G \) to \( R_H \), which preserves edges (if there is an edge numbered \( i \) between \( r \) and \( c \) in \( G \) then there is an edge numbered \( i \) between \( \pi(r) \) and \( \pi(c) \) in \( H \)) and may specialize labels (by observing type orders and allowing substitution of a generic marker by an individual one).

In the following, we use the notion of bicolored SG that was first introduced in [9]. A bicolored SG is an SG \( H = (H_0, H_1) \) in which a color on \( \{0, 1\} \) is assigned to each node of \( H \), in such a way that the subgraph generated by 0-colored nodes, denoted \( H_0 \) and called the core of \( H \), is a sub-SG. \( H_1 \), which is the sub-SG defined by 1-colored vertices and 0-colored concepts that are in relation with at least one 1-colored concept, is called the description.

3.2 Query framework

The chosen context is a base composed of assertions of entity existences and relations over these entities, called facts, and stored in a single graph (not necessarily connected) named the knowledge base. This graph is assumed to be normalized if it does not contain two individual nodes with the same marker \( i \). A normal form is easily computed by merging duplicate individual nodes of the graph. On the other hand, we do not require the KB graph to be in irredundant form: a graph \( G \) is in irredundant form if there is no a projection from \( G \) in one of these strict subgraphs; otherwise this graph is said to be in redundant form. Indeed, computation of the irredundant form of a graph is expensive as the base can be large [10] and, moreover, there is not any local criterion for computation of the irredundant form and thus no incremental method (started at each updating of the base) can be expected. Such a KB graph \( B \) is simply queried by specifying a
SG Q called the *query*. There is no constraint on the query (normalization or irredundancy). The answers to the query are found by computing the set $\Pi(Q, B)$ of projections from $Q$ to $B$. The primary notion of answer consists of returning the set of subgraphs of $B$ image of $Q$ by a projection in $\Pi(Q, B)$.

**Definition 1 (Answer set).** The set of answers of a query $Q$ in a base $B$, denoted $Q(B)$, is $\{\pi(Q) | \pi \in \Pi(Q, B)\}$.

The first research question we address in this paper is whether this set of answers contains redundant answers? In fact, three kinds of redundancies can arise:

1. **Duplication:** two answers are identical. There is a duplication when two projections define the same subgraph. This problem can be solved easily by only keeping one of the duplicate subgraphs (this is done in the answer set $Q(B)$). An example of duplication is given in fig. 3(b) taken as the KB and fig. 3(c) taken as the query: there are two projections from the query whose images are the whole KB.

2. **Inclusion:** An answer is contained in another one. There is an inclusion when an answer is in a redundant form. Then its subgraph, in irredundant form, is also an answer. In the previous example (fig. 3(b) and 3(c)), there are two projections that define included answers.

3. **Redundancy:** An answer is more general or equivalent than another one. There is a redundancy when two answers are comparable (thus the knowledge expressed by one is also expressed by another); as an example answers $A_1$ and $A_2$ of figure 1.

Inclusion will be studied in section 4.4. The true redundancy problem becomes crucial since the answers are no longer KB subgraphs. Indeed, two answers can appear redundant when they are not really redundant. In [2], we define the notion of redundancy based only on the comparability of the answer subgraphs. This approach was motivated by the following argument: as the returned set of answers is independent of the KB, the subset of the *more specific irredundant answers*, denoted $R_{\text{min}}$, is sufficient to bring the entire range of answers. Moreover, $R_{\text{min}}$ is minimal in terms of vertex number. In the following section, we characterize the true redundancy.

### 4 Dealing with true redundancy

In [2], the *completeness* criterion (the knowledge expressed by each initial answer is expressed by one of the answers contained in the returned subset of answers) ensures that no knowledge is lost when a redundant answer is deleted. But this redundancy is based only on the comparability of answer subgraphs (that are semantically close as they are specializations of the query).
4.1 The true redundancy

The true redundancy has to take the knowledge brought by the neighbor vertices of the answer into account. With this aim, we introduced the notion of extended answer, which is an answer supplemented with some knowledge extracted from its neighborhood.

**Definition 2 (Extension of an answer).** Let $B$ be a KB graph and $Q$ a query graph. An extension of an answer $A$ from $Q(B)$ is a bicolored graph $E = (E_0, E_1)$, where $E_0$ is isomorphic to $A$ and such that there is a projection $\pi$ from $E$ to $B$ with $\pi(E_0) = A$.

![Diagram](a) ![Diagram](b)

**Fig. 2.** Several extensions of answer $A_2$ of fig. 1.

Fig. 2 represents several extensions of answer $A_2$ of fig. 1. Note that the extensions are not necessarily isomorphic copies of subgraphs of the KB.

With the previous definition of redundancy (section 3.2), if two answers have two incomparable extensions, they are two distinct answers and thus have to be considered as non-redundant answers, the one w.r.t. the other one. However, these two answers must not be distinguished in an “artificial” way: i.e. if the answers are distinguished by selectively adding knowledge to the extension of only certain answers but not to all of those which possess this knowledge in their neighborhood.

**Definition 3 (Fairness property).** An extension $E$ of an answer $A$ from a set $Q(B)$ is fair iff there is no extension $E'$ of another answer $A'$ from $Q(B)$ such that there is a projection $\pi$ from $E$ to $E'$ with $\pi(E_0) = E'_0$ and $\pi(E_1) = E'_1$.

The extension of figure 2(b) is a fair extension of the answer $A_2$ of figure 1, contrary to the extension of figure 2(a). One can now give a definition of the true redundancy:

**Definition 4 (True redundancy).** An answer $A$ from a set of answers $Q(B)$ is truly redundant if there is no fair extension of this answer.

In the example of fig. 1, answer $A_1$ is redundant. The search for a fair extension may seem to be a difficult task, considering that the number of extensions that can be generated for an answer is infinite. However, these extensions are semantically bounded by a more specific one that corresponds to an isomorphic copy of the base, $(A, B \setminus A)^3$. Naturally, the more one adds knowledge to the

\[\text{For clarity, we sometimes denote subgraphs of KB as cores or descriptions of bicolored graph instead of their isomorphic copies.}\]
extension (the more it is specific), the more one potentially distinguishes this answer. So \( A \) is irredundant only if \( \langle A, B \setminus A \rangle \) is a fair extension.

**Theorem 1.** There is a fair extension \( E \) of an answer \( A \) iff \( \langle A, B \setminus A \rangle \) is a fair extension.

**Proof.** By contraposition. Suppose that there is a fair extension \( E = \langle E_0, E_1 \rangle \) of \( A \) and that \( \langle A, B \setminus A \rangle \) is not a fair extension of \( A \). \( \langle A, B \setminus A \rangle \) is an extension of \( A \) and is isomorphic (without considering the colors) to \( B \). As \( E \) is an extension of \( A \), there is a projection \( \pi \) from \( E \) to \( B \) such that \( \pi(E_0) = A \). As \( \langle A, B \setminus A \rangle \) is not a fair extension of \( A \), there is a projection \( \pi' \) from \( \langle A, B \setminus A \rangle \) to \( B \) such that \( \pi'(R_0) \neq A \). So there is a projection \( \pi'' = \pi \circ \pi' \) from \( E \) to \( B \) such that \( \pi''(E_0) \neq A \). Thus \( E \) is not a fair extension of \( A \).

\( \square \)

**Corollary 1.** An answer \( A \) of \( Q(B) \) is truly irredundant iff \( \langle A, B \setminus A \rangle \) is a fair extension.

4.2 The GRE problem

The problem of finding a fair extension of an answer is strongly related to the problem of generation of referring expressions (GRE) known in the natural language processing field, which aims to describe an object in a scene such that the description only refers to this object. The GRE problem was formalized in the CG framework in [4], where the scene is an SG and the object to identify is a concept of the SG. A referring graph of a concept \( v \) is a subgraph of the KB containing this concept, and a distinguishing graph is a referring graph whose \( v \) is a fixed point for all projections of the graph in the KB. Our problem of answer redundancy can be seen as an extension of this formalization.

**Definition 5 (Referring graph).** A referring graph of a subgraph \( G' \) of a graph \( G \) is a subgraph \( R \) of \( G \) that contains \( G' \) as a subgraph. To distinguish \( G' \) from the rest of the referring graph, we denote it as a bicolored graph \( R = \langle R_0, R_1 \rangle \) where \( R_0 = G' \) and \( R_1 = R \setminus G' \).

**Definition 6 (Distinguishing graph).** A referring graph \( R \) of a subgraph \( G' \) of a graph \( G \) is distinguishing if, for each projection \( \pi \) from \( R \) to \( G \), \( \pi(R_0) = G' \).

The referring graph of figure 2(b) is a distinguishing graph of the answer \( A_2 \) of figure 1, contrary of the referring graph of figure 2(a). We can now link the true redundancy notion with the existence of a distinguishing graph for a given answer. The next properties strengthen the notion of true redundancy by showing its independence in the query and thus in the other answers.

**Property 1.** Let \( A \) be an answer of \( Q(B) \). There is a fair extension of \( A \) iff there is a distinguishing graph of \( A \) w.r.t. \( B \).

**Proof.** Let \( E = \langle E_0, E_1 \rangle \) be a fair extension of \( A \). Then \( \pi(E) \) is a distinguishing graph of \( A \) w.r.t. \( B \). On the other hand, a distinguishing graph of \( A \) is also a fair extension of \( A \). \( \square \)
Corollary 2. An answer $A$ of $Q(B)$ is irredundant iff $R = \langle A, B \setminus A \rangle$ is a distinguishing graph of $A$ w.r.t. $B$.

Thus, determining whether an answer is irredundant can be done by testing the distinguishability of the referring graph built from KB. However, the cost of such a test is exponential in the size of the KB.

4.3 Redundancy and subset of answers

Since the redundancy of an answer has been defined, it could be considered that for building a set of answers without redundancies one could simply remove redundant answers. However, the redundancy defined in the preceding section hides the fact that they are two types of redundancy. This is shown in fig. 3 (a query and three different KBs):

The first case will arise when an answer is completely redundant with respect to another answer (fig. 3(b)). This means that $A_2$ is redundant w.r.t. $A_1$ but the reverse does not hold. In this case, we say that $A_2$ is strongly redundant w.r.t. $A_1$. Thus, we only return the answer $A_1$.

The second case arises when there are a set of answers which are redundant amongst themselves (fig. 3(c) and 3(d)). In these two examples, an answer is redundant with respect to the others and vice-versa. In this case, we say that the answers are mutually redundant and we have to choose an answer in this set.

Note that the answer redundancy problem still holds in KBs in irredundant forms, as in the example of fig. 3(d).

![Fig. 3. Different cases of redundant answers](image)

Strong and mutual redundancies are based on the redundancy of an answer w.r.t. another one:

**Definition 7 (Redundancy relation).** An answer $A$ is redundant to an answer $A'$ iff for each referring graph $R^A$ of $A$, there is a projection $\pi$ from $R^A$ to a referring graph $R^{A'}$ of $A'$ with $\pi(R^A_0) = \pi(R^{A'}_0) = A'$.
One can test the redundancy relation with the KB referring graph:

Property 2. An answer \( A \) is redundant to an answer \( A' \) iff there is a projection \( \pi \) from \( \langle A, B \setminus A \rangle \) to a referring graph \( R^{A'} \) of \( A' \) with \( \pi(A) = A' \).

Therefore an answer \( A \) is redundant to an answer \( A' \), the redundancy relation between \( A' \) and \( A \) defines the two previously seen redundancy cases:

Definition 8 (Redundancies between answers). Given \( A \) and \( A' \in \mathcal{Q}(B) \), such that \( A \) is redundant to \( A' \):
- \( A \) is strongly redundant to \( A' \) if \( A' \) is not redundant to \( A \);
- \( A \) and \( A' \) are mutually redundant if \( A' \) is redundant to \( A \);

Based on the notion of true redundancy, we can refine our notions of non-redundancy and completeness of subsets of answers that we defined in [2]:

Definition 9 (Non-redundant subset of answers). A subset of answers \( \mathcal{A} \) of \( \mathcal{Q}(B) \) is non-redundant if there are no two answers \( A \) and \( A' \in \mathcal{A} \) such that \( A \neq A' \) and \( A \) is redundant to \( A' \).

Definition 10 (Completeness). A subset of answers \( \mathcal{A} \) of \( \mathcal{Q}(B) \) is complete if for each answer \( A \) of \( \mathcal{Q}(B) \) there is an answer \( A' \) of \( \mathcal{A} \) such that \( A \) is redundant to \( A' \).

We define a graph of redundancies based on the notions of strong and mutual redundancies. All types of redundancies of definition 8 can be viewed as relations on \( \mathcal{Q}(B)^2 \), for example \( (A, A') \) belongs to the strong redundancy relation if \( A \) is strongly redundant to \( A' \). Thus we can characterize properties of these relations. Particularly, mutual redundancy defines equivalent classes over the set of answers, and strong redundancy links all answers of an equivalent class to all answers of another equivalent class. We construct the redundancy graph such that each vertex is an equivalent class, and is linked by the strong redundancy:

Definition 11 (Graph of redundancy). The graph of redundancy \( G = (V, E) \) of \( \mathcal{Q}(B) \) is a directed graph, where vertices represent equivalent classes of the mutual redundancy relation and where there is an edge between \( v_1 \) and \( v_2 \) if all answers of the class represented by \( v_1 \) are strongly redundant to all answers of the class represented by \( v_2 \).

Fig. 4(a) represents the redundancy graph of query and KB of fig. 1, whereas fig. 4(b) represents the redundancy graph of query of fig. 3(a) and KB defined by the union of KBs of fig. 3(b), 3(c) and 3(d).

![Redundancy Graphs](image-url)
To construct a complete and non-redundant set of answers, one has to only choose a single answer per equivalent class (to avoid mutual redundancy), only from equivalent classes that are sinks (to avoid strong redundancy), and for all of them (to be complete). This is why there is more than one non-redundant complete subset in the second example (fig. 4(b)): there is an equivalent class that is a sink and contains more than one element ({\(A_5, A_6\)}).

**Theorem 2.** A subset of answers \(A\) of \(Q(B)\) is complete and non-redundant iff for each sink in the redundancy graph there is a single answer of \(A\) that is represented by this sink.

**Proof.** Given a non-redundant and complete subset of answers \(A\). Non-redundancy means that there is a single answer for each equivalent class represented in \(A\) and that there are no two answers \(A_i\) and \(A_j\) such that there is a path from \(A_i\) to \(A_j\). Completeness ensures that for all answers \(A_i\) of \(Q(B)\) (particularly answers belonging to a sink) there is an answer \(A_j\) such that \(A_i\) is redundant to \(A_j\). So \(A\) has to contain an answer of each sink. When combining completeness and non-redundancy, only one answer of each sink is taken.

* Given a subset of answers \(A\) that is composed of an element of each sink of the redundancy graph. Given two answers of \(A\). These answers are not mutually redundant because there are no two answers of the same equivalent class. These answers are not strongly redundant because each answer comes from a sink. Thus \(A\) is non-redundant. For each answer \(A_i\) of \(Q(B)\), either there is an answer \(A_j\) of the same equivalent class in \(A\) (thus \(A_j\) is redundant to \(A_i\)), or there is an answer \(A_k\) in \(A\) that comes from a sink such that there is a path from the equivalent class of \(A_i\) to the sink, and thus \(A_i\) is redundant to \(A_k\). \(A\) is complete.

The construction of a redundancy graph combines the problem of finding all projections of a graph into another graph (to compute the set of answers) and the problem of computation of the irredundant form of a graph. Indeed, as stated by property 2, computation of all redundancy links of all answers used to construct the graph is based on all projections of the most specific referring graph of each answer (i.e. a bicolored isomorphic copy of the whole KB). Therefore, a way to compute all redundancy links is to compute all projections from the KB into itself, and check images of each answer by all projections.

### 4.4 Inclusion of answers

As mentioned in section 3.2, the inclusion of answers is one of the problems that can occur. If treated as a kind of duplication, included answers are just deleted from the answer set before computation of a non-redundant complete subset. But this approach is not the best one. We think that the inclusion problem should be treated after the redundancy problem.

In the example of fig. 5, there are seven answers: three that contain only one relation \((A_1, A_2, A_3)\), three that contain two relations \((A_{12}, A_{13}, A_{23})\), and \(A_{ij}\) Answer \(A_{ij}\) represents the answer that is the union of answers \(A_i\) and \(A_j\).
one with three relations \(A_{123}\). Considering all answers, only answers \(A_2\), \(A_3\) and \(A_{23}\) are irredundant (see fig. 5(c)), but it is not suitable to keep \(A_2\) and \(A_3\). Otherwise, if only non-included answers are kept, this leads to keeping answers that were redundant to deleted answers (here \(A_{123}\), redundant to \(A_{23}\)), which is not good.

Thus, we propose to restrict referring graphs of an answer to a portion of the base that is “near” this answer. This is also due to the fact that a referring graph that contains too much knowledge, even if it distinguishes an answer, does not help the user much. So we propose to bound referring graphs by a distance \(k\), and to only consider vertices that are in the distance field of one of the vertex of an answer, which forms the \(k\)-neighborhood graph of the answer:

**Definition 12 (\(k\)-neighborhood graph).** Given a KB \(B\), a subgraph \(S\) of \(B\), and a step \(k\) \((k \geq 0)\), the \(k\)-neighborhood graph, denoted \(N^k(S)\), is defined recursively by:

- \(N^0(S) = S\)
- \(N^{n+1}(S)\) is composed of \(N^n(S)\) expanded by every relation \(r\) not in \(N^n(S)\) and which is linked to a concept of \(N^n(S)\), and by all concepts linked to \(r\).

Recursion stops when \(n = k\) or \(N^n(S) = N^{n+1}(S)\) and returns \(N^n(S)\).

It seems obvious that all definitions put forward previously should now take this constraint into account. Bounding referring graphs can be seen as a restriction of the KB, which is now considered as the union of the \(k\)-neighborhood graph of each answer, for a given distance.

---

**Fig. 5.** A query and a KB that produce included answers, and their redundancy graph.

So the best way is to deal with redundancy first (by computing a subset that is non-redundant and complete) and to delete included answers after that. In the previous example, this strategy led to the subset \(\{A_{23}\}\).

### 4.5 Redundancy at a considered distance

In the query framework section, it was stated that computation of the irredundant form of the KB is a difficult problem. But we also see that computation of the redundancy graph also requires finding all projections of the KB into itself. Thus, we propose to restrict referring graphs of an answer to a portion of the base that is “near” this answer. This is also due to the fact that a referring graph that contains too much knowledge, even if it distinguishes an answer, does not help the user much. So we propose to bound referring graphs by a distance \(k\), and to only consider vertices that are in the distance field of one of the vertex of an answer, which forms the \(k\)-neighborhood graph of the answer:
Definition 13 (Truncated KB). Given a KB $B$, a query $Q$, and a distance $k \geq 0$, the truncated KB at distance $k$ is $B_k = \bigcup_{A \in Q(B)} N^k(A)$.

Now we can apply all previous definitions to the truncated KB. For example, an answer $A$ of $Q(B)$ is irredundant considering the distance $k$ iff $R = (A, B_k \setminus A)$ is a distinguishing graph of $A$ w.r.t. $B_k$ (see corollary 2).

5 Building smart answers

In the previous section, redundancy and completeness were only studied from a theoretical standpoint. A more user-aspect oriented standpoint was introduced in the section 4.5. Even if the user gets a subset of answers that is non-redundant and complete, he/she has no way to distinguish answers, i.e. the only assumption that can be made is that there is, for each answer, a way to distinguish them from the others. Otherwise, property 1 states that the most specific referring graph is one of them, but it usually contains too much knowledge.

So what are the properties of a really good set of referring graphs returned to the user? To keep the notions of non-redundancy and completeness, only answers of such a subset of answers should have a referring graph. As all of these answers can be distinguished, all referring graphs should be a distinguishing graph. Finally, to not introduce unnecessary redundancies in the set of referring graphs, there should be only one distinguishing graph by referred answer. A set of referring graphs that fulfills these properties is called a set of smart answers:

Definition 14 (Set of smart answers). A set of smart answers $S$ of a query $Q$ on a KB $B$ is a set of distinguishing graphs of all answers of a non-redundant complete set $A$ of $Q(B)$ such as $|S| = |A|$.

We propose the Bounded Smart Answers (BSA) algorithm (see algo. 1) that takes the answers and a distance as parameters, and returns a set of smart answers of truncated KB at distance $k$ such that each extension is the minimal $k$-neighborhood graph that distinguishes the answer.

Theorem 3. Algorithm BSA($Q(B), k$) produces a set of smart answers of $Q$ on the truncated KB $B_k$.

Proof. In DAK, all referring graphs are constructed with the same distance. Therefore, thanks to the distance conservation property of the projection, that if there is a bicolored projection from $N^k(A_i)$ to $N^k(A_j)$, there is a projection from $N^k(A_i)$ to $B_k$ such that image of the core of $N^k(A_i)$ is equal to $A_j$ (i.e. $N^k(A_i)$ is a referring graph of $A_j$ in $B_k$). For each answer $A$ that belongs to an equivalent class that is not a sink, $A$ will not be returned by DAK because of the second “foreach” of DAK. The third foreach of DAK ensures that for each equivalent class that is a sink, the algorithm will only add one (the first taken) answer that belongs to this class once the good distance is reached. Thus

\footnote{Note that comparisons in DAK (algo. 2) are between bicolored graphs, that is $B \leq B'$ if there is a $\pi$ from $B'$ to $B$ such that $\pi(B_0) = B_0$.}
Data: Answers $Q(B)$, a distance $k$

Result: A set of smart answers of truncated KB $B_k$

begin
  $i \leftarrow 0$
  $D \leftarrow \emptyset$ // distinguished answers
  $S \leftarrow \emptyset$ // smart answers
  while $i \leq k$ or $D \neq Q(B)$ do
    $D' \leftarrow \text{DISTING}_K(Q(B), D, i)$
    $D \leftarrow D \cup D'$
    foreach $A \in D'$ do
      $S \leftarrow S \cup \{(A, N^i(A) \setminus A)\}$
  return $S$
end

Algorithm 1: BOUNDED SMART ANSWERS (BSA)

the union of all answers returned by $DAK$ is a non-redundant complete subset of answers of $B_k$. As $BSA$ returns only one graph per answer of the computed non-redundant complete subset, $BSA$ returns a set of smart answers of $B_k$. $\Box$

6 Conclusion

We extended our previously defined notion of answer redundancy. Our new framework now considers answers but also descriptions (called referring graphs) that can distinguish an answer amongst others. These descriptions could be adapted to query languages of the semantic web, e.g. by giving a formal definition of the SPARQL $\text{DESCRIBE}$ query form. Therefore this new redundancy is now linked to the whole KB. Based on this new redundancy, we refined two other previous definitions concerning subsets of answers: non-redundancy property (there is no redundant answer in the subset) and completeness (each answer is redundant to an answer of the subset). We proposed a way to construct all non-redundant and complete subsets of answers using a redundancy graph. We introduced the notion of smart answer and gave an algorithm that computes a set of smart answers based on a vertex neighborhood distance.

Answer redundancy arises because of open world assumption and undefined objects (generic concepts). A deeper redundancy still exists, that is not related to the formalized world (the KB), but rather to the “real world” (described by the KB). For example, it is possible that non-redundant answers “a big cat” and “a white cat” refer to a single cat of the “real world”, which is big and white. The study of this new kind of redundancy can provide a foundation for using aggregation operators (e.g. number of results to a query) in graph based KB query languages.

ALASKA for Ontology Based Data Access

Jean-François Baget, Madalina Croitoru, Bruno Paiva Lima da Silva
LIRMM (University of Montpellier II & CNRS), INRIA Sophia-Antipolis, France

Abstract. Choosing the tools for the management of large and semi-structured knowledge bases has always been considered as a quite crafty task. This is due to the emergence of different solutions in a short period of time, and also to the lack of benchmarking available solutions. In this paper, we use ALASKA, a logical framework, that enables the comparison of different storage solutions at the same logical level. ALASKA translates different data representation languages such as relational databases, graph structures or RDF triples into logics. We use the platform to load semi-structured knowledge bases, store, and perform conjunctive queries over relational and non-relational storage systems.

1 Motivation and Impact

The ontology-based data access (ODBA) problem [4] takes a set of facts, an ontology and a conjunctive query and aims to find if there is an answer / all the answers to the query in the facts (eventually enriched by the ontology). Several languages have been proposed in the literature where the language expressiveness / tractability trade-off is justified by the needs of given applications. In description logics, the need to answer conjunctive queries has led to the definition and study of less expressive languages, such as the ELC ([1]) and DL-Lite families [2]. Properties of these languages were used to define profiles of the Semantic Web OWL 2 language (www.w3.org/TR/owl-overview).

When the above languages are used by real world application, they are encoded in different data structures (e.g. relational databases, Triple Stores, graph structures). Justification for data structure choice include (1) storage speed (important for enriching the facts with the ontology) and (2) query efficiency. Therefore, deciding on what data structure is best for one’s application is a tedious task. While storing RDF(S) has been investigated from a database inspired structure [3], other logical languages did not have the same privilege. Even RDF(S), often seen as a graph, has not been thoroughly investigated from a ODBA perspective wrt graph structures and emergence of graph databases in the NoSQL world.

This demo will allow to answer the following research question: “How to design an unifying logic-based architecture for ontology-based data access?”.

2 ALASKA

We thus demonstrate the ALASKA (acronym stands for Abstract and Logic-based Architecture for Storage systems and Knowledge bases Analysis) platform. ALASKA’s goal is to enable and perform ODBA in a logical, generic manner, over existing, heterogeneous storage systems. The platform architecture is multi-layered.
The first layer is (1) the application layer. Programs in this layer use data structures and call methods defined in the (2) abstract layer. Under the abstract layer, the (3) translation layer contains functions by which logical expressions are translated into the languages of several storage systems. Those systems, when connected to the rest of the architecture, compose the (4) data layer. Performing higher level reasoning operations within this architecture consists of writing programs and functions that use exclusively the formalism defined in the abstract layer. Once this is done, every program becomes compatible to any storage system connected to architecture.

To have a functional architecture, representative storage systems were selected. The systems already connected to ALASKA are listed below (please note that this list is not final and subject to constant updates):

- **Relational databases:** Sqlite 3.3.6\(^1\), MySQL 5.0.77\(^2\)
- **Graph databases:** Neo4J 1.8.1\(^3\), DEX 4.7\(^4\), OrientDB 1.0rc6\(^5\), HyperGraphDB 1.1\(^6\)
- **Triples Stores:** Jena TDB 0.9.4\(^7\)

Figure 1 displays, on the left-hand side, the class diagram of the architecture. On the right-hand side the workflow of knowledge base storing is illustrated. Let us analyse the workflow. We consider a RDF file as input. The RDF file is passed to the Input Manager (layer 1). According to the storage system needs the Input Manager directs it accordingly. If the RDF file will be stored in a Triple Store than the file is directly passed to the Triple Store of choice (layer 4). If the RDF file needs to be stored in a graph database the file is first transformed in an IFact object (layer 2). It is then translated (layer 3) to the language of the system of choice (graph database in this case) before being stored onto disk (layer 4).

Querying in ALASKA follows a similar workflow as the storage. In Figure 2, on the left hand side we show the storing workflow for storing a fact \( F \) in either a relational database or a graph database (for simplification reasons). On the right hand side of

\(^7\) http://jena.sourceforge.net/
the figure the querying workflow is depicted for graph and relational databases. Let us consider a fact $F$ both stored in a relational database and in a graph database. Let us also consider a query $Q$. This query can either be expressed in SQL (or in a graph language of choice) and be sent directly to the respective storage system (e.g. the SQL $Q$ query to the $F$ in the relational database). Alternatively, the query can be translated in the abstract logic language and a generic backtrack algorithm used for answering $Q$ in $F$. This generic backtrack algorithm will solely use the native language "elementary" operations for accessing data.

\end{array}$$

**Fig. 2.** ALASKA storage and querying workflow.

### 3 ALASKA Demo Procedure

In a nutshell, the demo procedure of ALASKA goes as follows. Given a knowledge base (user provided or selected amongst benchmarks provided by ALASKA) a set of storage systems of interest are selected by the user. The knowledge base is then transformed in the Abstract Architecture and consequently stored in the selected systems. The storage time per system is then showed to the user (excluding the time needed for translation into Abstract Layer). Once the storage step is finished, users are able to perform conjunctive queries over the knowledge bases and, once again, compare the time of each system for query answering.

Let us consider an example. The knowledge base used here has been introduced by the SP2B project [5]. The SP2B project supplies a generator that creates knowledge bases with a certain parametrised quantity of triples maintaining a similar structure to the original DBLP knowledge base. The generator was used to create 5 knowledge bases of increasing sizes (5 million triples, 20, 40, 75 and respectively 100). Each of the knowledge bases has been stored in Jena, DEX, SQLite and Neo4J. In Figure 3 we show the time for storing the knowledge bases and their respective sizes on disk.

The user can see that the behavior of Jena is worse than the other storage systems. This is due to the Jena RDF parser uses central memory for buffering purposes when loading a file. For comparison, the other systems use the custom made RDF parser of ALASKA. Let us also note that DEX behaves much better than Neo4J and this is due to the fact that ACID transactions are not required for DEX (while being respected by Neo4J). Second, the size of storage is also available to the user. One can see, for instance, that the size of the knowledge base stored in DEX and Neo4J is well under...
the size of initial RDF file. However, the size of the file stored in Jena is bigger than the one stored in SQLite and bigger than the initial size of the RDF file.

Once the storage step is finished, users are able to perform conjunctive queries. As already explained, querying the newly-stored knowledge base using the native interrogation engine (SQL for relational databases, SPARQL for 3Stores, etc.) is still possible with ALASKA. However, ALASKA also allows the possibility to perform conjunctive queries that access any storage system included in the platform using the same backtracking algorithm. The queries we have used here are:

1. `type(X, Article)`
   Returns all the elements which are of type article.
2. `creator(X, PaulErdoes) . creator(X, Y)`
   Returns the persons and the papers that were written with Paul Erdoes.
3. `type(X, Article) . journal(X, Journal1-1940) . creator(X, Y)`
   Returns the creators of all the elements that are articles and were published in Journal 1 (1940).
4. `type(X, Article) . creator(X, PaulErdoes)`
   Returns all the articles created by Paul Erdoes.

In the graphs in Figure 4 and 5 we show the combination storage and querying algorithm. For instance Jena(BT) stands for using Jena for elementary access operations and the generic backtracking for querying. SQLite(SQL) uses directly the SQL querying engine over the data stored in SQLite.

In the graph corresponding to Q1 we also study the behavior of SQLite using the generic backtracking. For other queries we did not show it because the behavior is much worse than the other systems. We can also observe that for Q1, Q3 and Q4 queries SQLite and Jena behave faster than the graph bases. However, for Q2 this is no longer the case. In this case the fastest system for the generic backtracking is Jena followed by Neo4J and DEX, while SQLite explodes. The intuition behind this behavior is due to the phase transition phenomenon in relational databases but these aspects are out of the scope of this demonstration.

4 Discussion

An abstract platform (ALASKA) was created in order to perform storage operations independently of the data location. In order to enable the comparison between different
storage paradigms, ALASKA has to translate a knowledge base from a common language (i.e. First Order Logic) into different other representation language. Comparing different storage and querying paradigms becomes then possible. A knowledge base stored in a relational database can be also stored in a graph based database as well as a Triple Store and queried with an in built SPARQL engine etc.

Coalitional Games via Network Flows

1 University of Southampton, UK  2 University of Oxford, UK  3 University of Warsaw, Poland  4 University of Montpelier, France

Abstract

We introduce a new representation scheme for coalitional games, called coalition-flow networks (CF-NETs), where the formation of effective coalitions in a task-based setting is reduced to the problem of directing flow through a network. We show that our representation is intuitive, fully expressive, and captures certain patterns in a significantly more concise manner compared to the conventional approach. Furthermore, our representation has the flexibility to express various classes of games, such as characteristic function games, coalitional games with overlapping coalitions, and coalitional games with agent types. As such, to the best of our knowledge, CF-NETs is the first representation that allows for switching conveniently and efficiently between overlapping/non-overlapping coalitions, with/without agent types. We demonstrate the efficiency of our scheme on the coalition structure generation problem, where near-optimal solutions for large instances can be found in a matter of seconds.

1 Introduction

Cooperation is a central concept in artificial intelligence and at the heart of multi-agent systems design. Coalitional game theory is the standard framework to model cooperation; it provides theoretical constructs that allow agents to take joint actions as primitives [Ieong and Shoham, 2006]. One of the most important research questions in this domain is the coalition structure generation problem (CSG), i.e., how can the set of agents be partitioned into groups (coalitions) such that social welfare is maximized? This problem has attracted considerable attention in the recent AI literature [Bachrach and Rosenschein, 2008; Michalak, et al., 2010; Rahwan et al., 2011], as it has important applications and inspires new theoretical and computational challenges. Existing work on coalition structure generation focuses on characteristic function games (CFGs), i.e., games in which the outcome obtained by a coalition is not influenced by agents outside the coalition.1

The prevailing assumption in CSG algorithms is that coalition structures are disjoint. However, there exist many realistic scenarios in which this assumption does not hold [Chalkiadakis et al., 2010]. For example, in multi-sensor systems, where sensors coordinate their movements to monitor particular targets of interest, the performance can be improved by allowing the sensors to form overlapping coalitions [Dang et al., 2006].

A second prevailing assumption in existing CSG algorithms is that every agent is unique, i.e., such works do not consider situations where some agents are identical. Again, the ability to differentiate between identical and non-identical agents can often improve performance. For example, in disaster response scenarios, one should distinguish between a fire brigade and an ambulance (as they are aimed for different activities), but may be indifferent between two ambulances with equal capabilities. The theory of coalition structure generation has been extended only recently to such domains [Aziz and de Keijzer, 2011; Ueda et al., 2011].

The standard CFG representation explicitly lists the values of all the possible coalitions and requires space that is exponential in the number of agents. However, in many classes of games, there exists additional structure (such as identical agents) that can be exploited, and well-crafted representation schemes can significantly improve performance [Deng and Papadimitriou, 1994; Ieong and Shoham, 2006; Elkind et al., 2009; Aadithya et al., 2011]. However, the majority of works in this line of research focused on computing solution concepts, rather than solving the coalition structure generation problem.

To date, with very few exceptions (e.g., [Shehory and Kraus, 1998; Dang and Jennings, 2006]) the incorporation of tasks is absent from the research on coalition structure generation. The advantage of incorporating tasks is that it allows for capturing a much wider range of applications. In particular, many real-world applications involve a set of tasks to be achieved, where the agents need to form coalitions since (some of) those tasks cannot be performed by an individual agent, or can be achieved more efficiently by a group of agents (compared to an individual). However, the disadvantage of incorporating tasks is that it makes the optimization problems (such as coalition structure generation) significantly harder to solve. This is because the value of a coalition does

1Recently, a coalition structure generation algorithm has been proposed in games with “externalities” (i.e., possible influences between co-existing coalitions) [Rahwan et al., 2012].
not depend solely on the identities of its members; it depends on the tasks being achieved by the coalition. As such, a coalition does not necessarily have a single value. Instead, it can have a different value for every task.

Our Contribution

We formulate a unified approach for modelling different types of coalitional games in task-based settings. In particular, we formulate the coalition structure generation problem as a network flow problem—a problem widely studied in the combinatorial optimization literature, with many important applications in the real world [Schrijver, 2003]. More specifically:

- We propose a new representation of coalitional games, namely coalition-flow networks (CF-NETs), where the coalition formation process is represented as the process of directing the flow through a network with edge-capacity constraints. We show that CF-NETs are an appropriate representation for several important classes of coalitional games, such as conventional (non-overlapping) coalitional games, overlapping coalitional games, and coalitional games with agent types. Importantly, to the best of our knowledge, this is the first representation with which one can easily and efficiently switch between cases with overlapping/non-overlapping coalitions, with/without agent types. In addition, we show how CF-NETs allow for the succinct storage of certain, potentially useful patterns.

- We show that under the CF-NET representation, the coalition structure generation problem in a task-based setting can be reformulated as a mathematical program related to the well-known production-transportation problem [Tuy et al., 1996; Holmberg and Tuy, 1999; Hochbaum and Hong, 1996].

- We provide an anytime approximation technique for the CSG problem, which provides worst-case guarantees on the quality of the solutions produced. Using numerical simulations, we show that our algorithm scales to thousands of agents. For example, for \( n = 5000 \) agents, it finds solutions within 75-85% of the optimum in a matter of seconds.

Related Work

Researchers have attempted to circumvent the intractability of the characteristic function form by developing alternative representations, which are more compact and allow efficient computations. These representations can be divided into two main categories:

1. The representation is guaranteed to be succinct, but is not fully expressive (i.e., it cannot represent any arbitrary characteristic function game) [Deng and Papadimitriou, 1994; Wooldridge and Dunne, 2006].

2. The representation is fully expressive, but is only succinct for some problem instances [Ieong and Shoham, 2006; Elkind et al., 2009; Conitzer and Sandholm, 2004b]. Our CF-NET representation scheme falls in this category.

Most previous work focuses on the computation of solution concepts, such as the Shapley value [Deng and Papadimitriou, 1994; Ieong and Shoham, 2006; Elkind et al., 2009; Conitzer and Sandholm, 2004b], the core [Conitzer and Sandholm, 2004a; 2004b], the bargaining set, and the kernel [Greco et al., 2009]. On the other hand, the coalition structure generation problem has recently attracted attention, with most of the studies focusing on characteristic function games [Rahwan et al., 2009].

Among the very few works that consider overlapping coalitions, we mention the works by Shelly and Kraus [1996] and Dang et al. [2006]. The former only proposes a greedy algorithm for a subclass of these games, whereas the latter makes heavy use of several strong assumptions placed on the characteristic function. Recently, Chalkiadakis et al. [2010] introduced a formal model of overlapping coalition formation, in which an agent can participate in multiple coalitions simultaneously, by contributing a portion of its resources to each coalition containing it.

Our CF-NET representation is designed for the purpose of solving the coalition structure generation problem efficiently. The only other representation designed with this problem in mind is due to Ohta et al. [2009]. However, unlike our representation, theirs does not incorporate tasks, and does not consider games with agent types or overlapping coalitions.

The basic idea of applying network flows to model coalitional games has been examined before, for example by Kalai and Zemel [1982] and by Bachrach and Rosenschein [2009]. However, the fundamental difference is that, in those papers, the units of flow can be thought of as utility units (so the solution to a network flow problem influences the value of a coalition). In our representation, what flows in the network is “agents”, so solving a flow problem returns a coalition structure. This is precisely what gives flexibility to our framework, allowing for overlapping coalitions, or identical agents, to be considered whenever needed.

2 Preliminaries

In this section, we provide the standard definitions for the classes of coalitional games studied in this work.

We define a task-based characteristic function game, TCFG, as a coalitional game given by a tuple \( \langle A, K, v \rangle \), where

\[ A = \{a_1, \ldots, a_n\} \] is a set of agents;

\[ K = \{k_1, \ldots, k_m\} \] is a set of tasks;

\[ v : 2^A \times K \rightarrow \mathbb{R} \] is a function that assigns a value to every pair \( (C, k_i) \), where \( C \) is a coalition and \( k_i \) is a task.

In this paper, we assume that every performed task is performed by exactly one coalition. The possibility of having a group of agents that does not perform any tasks can easily be incorporated by adding a single dummy task. On the other hand, the possibility of having a single coalition perform multiple tasks can be incorporated by allowing overlapping coalitions (in which case every performed task is performed by a single, not necessarily unique, coalition).

An implicit assumption is that every agent can participate in exactly one coalition. When an agent is allowed to belong to multiple coalitions simultaneously, the tuple \( \langle A, v \rangle \)
defines a task-based coalitional game with overlapping coalitions, denoted by TCFG\(^\omega\). In such a game, each agent can be a member of up to \(2^{n-1}\) coalitions. In reality, this number is reasonable only if coordination costs are low and the number of available resources is sufficiently large.

Thus, the definition can naturally be extended to a task-based resource-constrained coalitional game with overlapping coalitions (TCFG\(^\omega\)). In such a game, each agent \(a_i \in A\) has an upper bound on the number of coalitions it can join, which can be interpreted as a limit on the resources that can be employed by an agent to perform tasks. In this setting, a game is formally defined by a tuple \((A, r, v)\), where \(A\) and \(v\) are defined as above, and the function \(r: A \rightarrow \{1, \ldots, 2^{n-1}\}\) assigns to every agent its resource constraints.\(^{5}\) Note that the TCFG\(^\omega\) and TCFG representations are special cases of TCFG\(^\omega\), where the number of coalitions that an agent can join is maximal \((2^{n-1})\) and minimal \((1)\), respectively.

Next, we formalize task-based coalitional games with agent types. Let \(A\) be a set of agent types, \(n\) be the maximum number of different tasks a coalitional game with agent types \(A\) can represent, \(\tau\) be a set of agent types, and \(t\) be a function that returns the type of any agent. An important situation to model in such games is that of two types \((\tau)\) to represent the classes of coalitional games discussed above.

**Definition 2** A coalition-flow network (CF-NET) is a tuple \((N, E, X, Y, Z)\), where \((1)\) \((N, E)\) is an acyclic digraph with a set of nodes \(N\) and a set of directed edges \(E\), and \((2)\) \(X, Y\) and \(Z\) are sets of constraints. In particular:

1. **The set of nodes,** \(N\), is the union of the following disjoint sets:
   - \(\{S, G\}\) contains the source node \(S\) from which the "flow" is pushed into the network and the sink node \(G\) towards which the flow needs to be directed.
   - \(N^a\) is the set of agent nodes: each agent (or type) is represented by exactly one such node. As such, \(|N^a| = n\).
   - \(N^k\) is the set of task nodes: each task is represented by exactly one such node. Thus, \(|N^k| = q\).
2. **The set of edges** is \(E = (\{(S \times N^a) \cup E\} \cup (N^k \times \{G\}))\), where \(E = \{(n_i, n_j) : n_i \in N^a, n_j \in N^k\}\).
3. **The set of constraints** is \(X \cup Y \cup Z\), where \(X = \{X_i : i = 1 \ldots n\}\), \(Y = \{Y_j : j = 1 \ldots q\}\), and \(Z = \{Z_j : j = 1 \ldots q\}\), which restrict the possible values of the flow through the edges in \((S) \times N^a\), \(E\), and \(N^k \times \{G\}\), respectively. In particular:
   - \(X_i\) represents the permitted multiplicities of agent \(a_i\) (or the permitted numbers of agents of whose type is \(t_i\)) in the game.
   - \(Y_j\) represents the permitted multiplicities of agent \(a_i\) (or permitted numbers of agents of type \(t_i\)) that will perform task \(k_j\).
   - \(Z_j\) represents the sizes of the coalition that will perform task \(k_j\).

An illustration of the CF-NET representation can be found in Figure 1. Now, based on the network structure \((N, E)\) defined above, and the constraints \(X \cup Y \cup Z\) imposed on the flow through the edges, we introduce the next notion of CF-flow. Intuitively, the CF-flow depicts the coalition formation process. Analogously to the flow in the network, the process of directing the flow from the source node to the sink node (through the agent/type nodes and the task nodes) can be interpreted as the process of determining which coalition should perform each task.

**Definition 3** A coalition formation flow (CF-flow) in a CF-NET \((N, E, X, Y, Z)\) is a function \(f: E \rightarrow \mathbb{R}\) with the following properties:

1. \(f(S, n_i) \in X, \forall n_i \in N^a\).
2. \(f(n_i, n_j) \in Y, \forall (n_i, n_j) \in E\).
3. \(f(n_j, G) \in Z, \forall n_j \in N^k\).
4. \(\sum_{(n_i, n_j) \in E} f(n_i, n_j) = \sum_{(n_j, n_k) \in E} f(n_j, n_k)\), \(\forall n_j \in N^a \cup N^k\).

Let \((x, y, z)\) be an instantiation of a CF-flow \(f\) in a CF-NET \((N, E, X, Y, Z)\), such that \(x_i = f(S, n_i)\) for \(n_i \in N^a\), \(y_j = f(n_i, n_j)\) for \((n_i, n_j) \in E\), and \(z_j = f(n_j, G)\) for \(n_j \in N^k\). Then, from Definition 3, we have:

\[
x_i = \sum_{j=1}^{n} y_{ij} \quad \forall i = 1, \ldots, n; \quad z_j = \sum_{i=1}^{m} y_{ij} \quad \forall j = 1, \ldots, m; \quad (1)
\]

\[
x_i \in X_i, \quad y_{ij} \in Y_{ij}, \quad z_j \in Z_j, \quad \forall i = 1, \ldots, n; \quad \forall j = 1, \ldots, m.
\]
Given a CF-flow, we define next the values of the coalitions constructed by it. To this end, we equip a CF-NET with three valuation functions as follows:

**Definition 4** Given a CF-NET \( \langle N, E, A, Y, Z \rangle \), let \( c, d, g \) be the valuation functions defined, respectively, on \( \{S \times N\} \times N^k \times \{G\} \), such that:

- For all \( (S, n) \in \{S\} \times N^k \), \( c_i = c(S, n) \) represents the value of a singleton coalition of agent \( a_i \) (or an agent of type \( t_i \)).
- For all \( (n, n) \in \{S\} \times N^k \), \( d_{ij} = d(n, n) \) is the contribution of agent \( a_i \) (or an agent of type \( t_i \)) to task \( k_j \).
- For all \( (n, G) \in \{S\} \times \{G\} \), \( g_j(z_j) = g(n, G) \) is a synergy function, where \( z_j \in Z \) is the size of the coalition performing task \( k_j \).

That is, the value of a coalition \( C \) performing task \( k_j \) is given as:

\[
v(C, k_j) = \sum_{n \in C} d_{ij}y_{ij} + g_j(|C|).
\]

(2)

The first advantage of CF-NETS is their ability to represent any of the four classes of games discussed above, i.e., TCFG, TCFG\(^o\), TCFG\(^oo\), and TCFG\(^d\). This can be done simply by setting the appropriate \( X, Y, \) and \( Z \). In more detail,

- In TCFG, \( \forall n_i \in A, X_i = \{1\}, \forall n_i \in A, \forall k_j \in K, Y_{ij} = \{0, 1\}, \) and \( \forall k_j \in K, Z_j = \{0, \ldots, n\} \);
- In TCFG\(^d\), \( \forall n_i \in A, X_i = \{1, \ldots, 2^{n-1}\}, \forall n_i \in A, \forall k_j \in K, Y_{ij} = \{0, 1\}, \) and \( \forall k_j \in K, Z_j = \{0, \ldots, n\} \);
- In TCFG\(^oo\), \( \forall n_i \in A, X_i = \{1, \ldots, r(a_i)\}, \forall n_i \in A, \forall k_j \in K, Y_{ij} = \{0, 1\}, \) and \( \forall k_j \in K, Z_j = \{0, \ldots, n\} \);
- In TCFG\(^d\), \( \forall n_i \in A, X_i = \{|T_i|\}, \forall n_i \in A, \forall k_j \in K, Y_{ij} = \{0, \ldots, |T_i|\}, \) and \( \forall k_j \in K, Z_j = \{0, \ldots, n\} \).

Next, we discuss expressiveness.

**Proposition 1** Every coalitional game that can be modelled as a TCFG, TCFG\(^d\), TCFG\(^oo\) and/or TCFG\(^d\), can be also represented as a CF-NET.

---

**Proof:** We demonstrate that, for any arbitrary coalitional game under consideration, there exists a CF-NET representation that uniquely defines this game. Specifically:

1. **TCFG:** Our aim is to construct CF-NET representing an arbitrary game \( \langle A, K, v \rangle \). First, we create a one-to-one function \( I : 2^k \times K \rightarrow \{1, \ldots, 2^k \times q\} \).
   Now, for each coalition \( C \in 2^k \) and task \( k_j \in K \), we create a hypothetical task \( w_j(C,k_j) \) which is connected to all the agents in \( C \) and none of the agents in \( A \backslash C \). Moreover, for every \( a_i \in C \), we set \( X_i = \{1\}, Y_{ij} = \{0, 1\}, \) and \( d_{ij} = 0 \). We also set \( g_j(C,k_j) = 0 \), and \( g_j(C,k_j) \) on \( (C) \) is \( v(C, k_j) \) and \( g_j(C,k_j) \) on \( (0) \) is \( 0 \).

2. **TCFG\(^o\)/TCFG\(^oo\):** This case is similar to the previous one. The difference is only in the definition of \( X_i \), which is now given by \( X_i = \{1, \ldots, 2^k \} \) in the case of TCFG\(^o\), or \( X_i = \{1, \ldots, r(a_i)\} \) in the case of TCFG\(^oo\).

3. **TCFG\(^d\):** Here, agent nodes depict available types of agents. That is, every node \( n_i \in \{N\} \) represents a type \( t_i \). This case is similar to TCFG case, except that we now set \( X_i = \{|T_i|\} \) and \( Y_{ij} = \{0, \{C \cap T_i\}\} \).

The constructs in the proof of Proposition 1 imply that CF-NETS are no less concise than the corresponding TCFG, TCFG\(^o\)/TCFG\(^oo\) and TCFG\(^d\) representations. Indeed, the edges do not need to be explicitly represented; for every hypothetical task \( w_e \) it is possible to identify it simply by using the inverse of function \( I \) (which in turn can be concisely represented).

Observe that, for certain patterns often encountered in coalitional games, CF-NETS provide much more concise representations. For instance, suppose there exist additional requirements for coalitions to be formed, such as certain agents being compatible with each other, or constraints on the coalition sizes. In these cases, one can simply exclude “infeasible” coalitions from the set of coalition nodes. This only decreases the size of the representation, which for certain game classes makes CF-NETS exponentially more concise than the corresponding characteristic function representations.

Next we prove our main technical result, demonstrating the computational power of the CF-NET representation in the coalition structure generation problem.

---

**4 Coalition Structure Generation in CF-NETS**

In this section, we formally define the coalition structure generation (CSG) problem and propose an approximation method for solving it on CF-NETS. Our technique utilizes the advantages of the CF-NET representation to produce anytime solutions and estimate their quality.

**The CSG Problem**

First, we make explicit the notion of a coalition structure for each of the classes TCFG, TCFG\(^d\), TCFG\(^oo\) and TCFG\(^d\).

1. **TCFG:** A coalition structure, \( \pi \), is a partition of the agents:

\[
\pi = \left\{ C : C \subseteq A, \bigcup_{C \in \pi} C = A, \forall C, C' \in \pi : C \cap C' = \emptyset \right\}
\]

3Throughout the paper this is assumed that \( g_j(0) = 0 \).
2. TCFG: Similar to TCFG, except that coalitions can now overlap. A coalition structure, \( \pi^* \), is defined as:
\[
\pi^* = \left\{ C : C \subseteq A, \bigcup_{C \in \pi} C = A \right\}
\]

3. TCFG\( ^{\text{co}} \): In this case, each agent \( a_i \in A \) can belong to at most \( r(a_i) \) coalitions simultaneously:
\[
\pi^{\text{co}} = \left\{ C : C \subseteq A, \bigcup_{C \in \pi} C = A, \forall a_i \in A : \left| \left\{ C \in \pi : a_i \in C \right\} \right| \leq r(a_i) \right\}
\]

4. TCFG\( ^{\text{m}} \): Coalitions are multi-sets of types, rather than sets of agents as in previous cases. Let \( m_y(x) \) denote the multiplicity of element \( x \) in multi-set \( y \), then:
\[
\pi^{\text{m}} = \left\{ C : C \subseteq T, \bigcup_{C \in \pi} C = T, \forall t \in T : \sum_{C \in \pi} m_y(t) = m_T(t) \right\}
\]

Let \( \Pi^d \) denote the sets of all possible coalition structures in TCFG\( ^d \), where index \( x \) is either empty or stands for "o", "rco" or "at". The CSG problem in TCFG\( ^d \) is to find an optimal coalition structure, \( \pi^*_d \), that maximizes the sum of coalition values:
\[
\pi^*_d = \arg \max_{\pi \in \Pi^d} \sum_{C \in \pi} v(C_i, k_i).
\]

Solving the CSG Problem in CF-NETs

We now formalize the CSG problem in terms of CF-NETs. Here, since the value of a coalition performing a task is defined by (2), the value of a coalition structure is:
\[
\sum_{i=1}^{n} \sum_{j=1}^{q} d_{ij} y_{ij} + \sum_{j=1}^{q} g_j(z_j).
\]

For ease of exposition, we focus next on the non-overlapping model. However, we emphasize the fact that our method can be easily extended to games with overlapping coalitions or with agent types (by defining \( X_t, Y_{ij} \) and \( Z_j \) accordingly).

For all \( i, j \), we have \( X_t = \{1\}, Y_{ij} = \{0, 1\} \) and \( Z_j = \{0, \ldots, n\} \). The coalition structure generation problem can then be formulated as a mathematical program:

\[
\begin{align*}
\text{CSG} & : \quad \max_{x, y, z} \sum_{i=1}^{n} \sum_{j=1}^{q} d_{ij} y_{ij} + \sum_{j=1}^{q} g_j(z_j) \\
\text{s.t.} & : \quad z_j = \sum_{i=1}^{n} y_{ij}, \quad \forall j = 1, \ldots, q, \quad (3) \\
& : \quad x_i = \sum_{j=1}^{q} y_{ij}, \quad \forall i = 1, \ldots, n, \quad (4) \\
& : \quad x = \{1\}^n, \quad y \in \{0, 1\}^{n \times q}, \quad z \in \{0, \ldots, n\}^q. \quad (5)
\end{align*}
\]

Note that if the synergy functions \( g_j \) are linear, the problem is equivalent to the classical maximum network flow problem and can be solved efficiently [Cormen et al., 2001]. However, for non-linear synergies, CSG becomes a non-linear integer programming problem, which is generally NP-hard [Sandholm et al., 1999]. In this paper, we solve/approximate CSG for general synergy functions.

First, observe that our problem is related to the production-transportation problem from Operations Research [Tuy et al., 1996; Holmberg and Tuy, 1999], which also has a network flow interpretation. Here, the non-linear terms \( g_j(z_j) \) can be viewed as the production part that the decision makers have to decide upon. Once the production \( z \) has been fixed, the problem becomes a standard transportation problem – of finding \((x, y) – and can be solved efficiently. However, solving for optimal \((x, y) \) and \( z \) simultaneously is non-trivial [Hochbaum and Hong, 1996].

Therefore, in this work we develop an approximation technique for CSG. Our method has two advantages: it gives an anytime algorithm and it provides upper and lower bounds on the optimal value; as a result, one can quantify how far the solution provided is from the optimal solution. Specifically, we use constraint relaxation and duality to modify the mathematical program as follows.

Relax the constraint (3) \( z_j = \sum_{i=1}^{n} y_{ij} \) in CSG and consider the corresponding dual problem:

\[
\begin{align*}
\min_{\lambda} & : \quad \max_{x, y, z} \sum_{i=1}^{n} \sum_{j=1}^{q} d_{ij} y_{ij} + \sum_{j=1}^{q} g_j(z_j) \\
& - \sum_{j=1}^{q} \lambda_j(z_j - \sum_{i=1}^{n} y_{ij}) \\
\text{s.t.} & : \quad (4), (5)
\end{align*}
\]

Now, for each fixed \( \lambda \), consider the inner problem:

\[
\begin{align*}
h(\lambda) & : \quad \max_{x, y, z} \sum_{i=1}^{n} \sum_{j=1}^{q} (d_{ij} + \lambda_j) y_{ij} \\
& + \sum_{j=1}^{q} (g_j(z_j) - \lambda_j z_j) \\
\text{s.t.} & : \quad (4), (5)
\end{align*}
\]

By replacing every \( x_i \) with \( \sum_{j=1}^{q} y_{ij} \) and noticing that \( h(\lambda) \) is now separable in \( y \) and \( z \), we can show that

\[
h_{1x}(\lambda) = \max_{y, z} \sum_{i=1}^{n} \sum_{j=1}^{q} (d_{ij} + \lambda_j) y_{ij} \\
\text{s.t.} \quad \sum_{j=1}^{q} y_{ij} \leq 1, \\
h_{2z}(\lambda) = \max_{y, z} \sum_{i=1}^{n} \sum_{j=1}^{q} g_j(z_j) - \lambda_j z_j.
\]

Finally, by simplifying \( h_{1x}(\lambda) \) to \( h_{1z}(\lambda) = \max_{y, z} \{d_{ij} + \lambda_j\} \), we get a one variable integer programming problem, which can be easily solved.

Thus, for each fixed \( \lambda \), we can compute \( h(\lambda) \) very efficiently. Notice that \( \min_{\lambda} h(\lambda) \) provides an upper bound on CSG (duality theory) and hence any choice of \( \lambda \) gives
an upper bound (but we are interested in the smallest one, $\min_{x} h(\lambda(x))$). Notice also that $h(\lambda)$ is a piece-wise linear function on $x$ with possible jumps. We then can solve the problem $\min_{x} h(\lambda(x))$ using a sub-gradient based method for updating $\lambda$, i.e., we reduce $\lambda_i$ if $\sum_{i=1}^{n} y_{ij} < 0$ and increase $\lambda_i$ otherwise. Although we might not be able to solve $\min_{x} h(\lambda(x))$ to optimality, a sub-optimal solution still provides us with an upper bound on $CSG$.

Finally, lower bounds are obtained. First, for each $\lambda$, the inner problem can be solved to find its optimal solution on $(x, y, z)$. This solution is a feasible solution to $CSG$ and hence its objective value provides a lower bound. Another method for producing a lower bound is to fix the optimal $z$ found in the inner problem and then solve the transportation problem to find the corresponding optimal $(x, y)$. This will give another feasible solution and hence, a new lower bound.  

5 Performance Evaluation

We perform numerical tests on the algorithm for various settings with the number of agents $n$ varying between 100 and 5000 and the number of tasks $q$ varying between 50 and 200. For each combination of $(n, q)$, we generate 100 random samples using random seeds between 1 and 100. In total, we have tested the algorithm with 2000 random instances. On each instance, the parameters $c$ and $d$ are generated uniformly, i.e., $d_{ij} \sim U[0, 1]$. The synergy function $g_j(z_j)$ is also a random discrete function of the following form:

$$g_j(z_j) = \epsilon_{j1} + \epsilon_{j2} + \ldots + \epsilon_{jk}, \quad \forall k = 1 \ldots n, \forall j = 1 \ldots q,$$

where $\epsilon_{ji} \sim U[0, 1]$ are uniform random variables. This means the synergy function $g_j$ is the sum of uniform random variables and the coalition value increase by $\epsilon_{ji}$ when the coalition size increases from $s - 1$ to $s$. By creating 100 random instances, we can test the robustness of the algorithm when input data varies.

Figure 2 shows the performance of the algorithm when the number of agents varies between 100 and 5000, while the number of tasks is fixed at 100. Sub-figure (A) shows the total computational time, sub-figure (B) shows the number of iteration, while sub-figure (C) shows the optimality bound between the feasible coalition structure found and the worst upper bound. We can see a linear trend in the computational time from sub-figure (A) with less than three minutes to solve the largest and the worst instance (among 600 random instances for this case). The linear trend in the computational time can be explained by the fact that the number of arithmetic operations in each iteration grows linearly, while the number of iterations (shown in sub-figure (B)) does not change much.

Sub-figure (C) shows the guaranteed bound between the feasible coalition structure found and the optimality. Notice that these bounds are guaranteed despite the fact that we don’t know the optimal coalition structures thanks to the availability of the upper bounds derived by the algorithm. This also means that the actual optimality bounds could be higher than the average optimality bounds between 75-81% that appear in sub-figure (C).

Figure 3 shows the performance of the algorithm when the number of agents varies is fixed at $n = 2000$, while the number of tasks varies between 50 and 200. We can see a very similar linear trend in the computational time in sub-figure (A) and the optimality bounds between 75-81% in sub-figure (C). The total computational time for the largest instance is less than 35 seconds.

Figures 4, 5 show the same set of statistics as in Figures 2, 3 except that the CFG games now allow each players to join up to 5 coalitions. The guaranteed optimality bounds vary between 76-85% on these instances. We can also see a linear trend in the computational time as the number of players and the number of tasks increase and the algorithm takes less than 90 seconds for the worst instance.

6 Conclusions

We introduced CF-NETS, a representation scheme for coalitional games in task-based settings, which is inspired by network flows. We examined its qualities with respect to conventional coalitional games with non-overlapping coalitions, (resource-constrained) overlapping coalitional games, and coalitional games with agent types. We utilized the advantages of this representation to develop an approximation technique for coalition structure generation, which applies to all these game classes and allows to effectively solve large instances of the problem.

Our work can be extended in several ways. It would be interesting to extend the CF-NET framework with components that would allow to capture game patterns other than those considered in this paper. Furthermore, we are keen on testing the properties of the CF-NET representation with respect to computing different solution concepts such as the Shapley value and the core.

Information Revelation Strategies in Abstract Argument Frameworks using Graph based Reasoning

Madalina Croitoru\(^1\), Nir Oren\(^2\)

Abstract. The exchange of arguments between agents can enable the achievement of otherwise impossible goals, for example through persuading others to act in a certain way. In such a situation, the persuading argument can be seen to have a positive utility. However, arguments can also have a negative utility — uttering the argument could reveal sensitive information, or prevent the information from being used as a bargaining chip in the future. Previous work on arguing with confidential information suggested that a simple tree based search be used to identify which arguments an agent should utter in order to maximise their utility. In this paper, we analyse the problem of which arguments an agent should reveal in more detail. Our framework is constructed on top of a bipolar argument structure, from which we instantiate bonds — subsets of arguments that lead to some specific conclusions. While the general problem of identifying the maximal utility arguments is \(NP\)-complete, we give a polynomial time algorithm for identifying the maximum utility bond in situations where bond utilities are additive.

1 Introduction

When participating in dialogue, agents exchange arguments in order to achieve some goals (such as convincing others of some fact, obtaining a good price in negotiation, or the like). A core question that arises is what arguments an agent should utter in order to achieve these goals. This dialogue planning problem is, in most cases, computationally challenging, and work on argument strategy [2, 6, 7, 9] has identified heuristics which are used to guide an agent’s utterances.

In this paper we consider a scenario where an agent must select some set of arguments to advance while taking into account the cost, or benefit, associated with revealing the arguments. [7] deals with a similar situation, and give the example of a government attempting to convince the public that weapons of mass distraction exist in some country. They assume that doing so will result in a positive utility gain. In order to back up their claims, the government must give some further evidence, and have a choice of arguments they can advance in doing so, ranging from citing claims made by intelligence resources on the ground, to showing spy satellite photographs, to withdrawing the claims. Each of these arguments has an associated utility cost, and the government must therefore
identify the set of arguments which will maximise its utility. In such a situation, it is clear that advancing all arguments is not always utility maximising for an agent, and [7] utilise a one-step lookahead heuristic to maximise utility while limiting computational overhead.

Unlike [7], in this paper we assume that an agent can advance several arguments simultaneously within a dialogue, and must justify these arguments when advancing them. We therefore seek to identify all arguments that an agent must advance at a specific point in time. To do so, we utilise a bipolar argument framework [3] to allow us to deal with both attacks between arguments and argument support.

We solve our problem through a translation of the argument structure into a graph structure, and then utilise graph operations in order to calculate the appropriate set of arguments to advance. Such a translation also allows us to derive an interesting result with regards to the complexity of bonds calculation.

In the next section we introduce the concept of a bond — a set of arguments that should be introduced together by an agent. We then examine the problem of computing a maximum utility bond. The paper concludes with a discussion of possible extensions.

2 Bonds

An argument can have several possible justifications. In the context of a dialogue, it is clearly desirable to advance the maximal utility justification. Importantly, this justification often does not coincide with the maximal justification in the set theoretic sense, as the utility of the entire set of arguments might be smaller than the utility of a subset of these arguments. A bond is then precisely the maximal utility justification for an argument. This is illustrated by the following informal example.

**Example 1.** A student is asked to justify why they did not hand in their homework on time, and can respond in several ways. First, they could claim they had done the homework, but that their new puppy ate it. Second, they could explain that they were ill. Furthermore, they could blame this illness on either a nasty virus they had picked up, or due to a hangover caused by over exuberance during the weekend. Clearly, providing all these reasons will not engender as much sympathy as simply blaming the virus. The latter therefore forms a maximal utility justification aimed at obtaining the teacher’s sympathy, and forms a bond.

Bonds originate through the possibility that multiple lines of argument yield the same result, and that some of these have different utility costs and benefits when compared to others. A bond is made up of the subset of paths that maximise the agent’s utility.

We situate bonds within Bipolar argumentation frameworks [1]. Unlike standard Dung argumentation frameworks, bipolar frameworks explicitly consider both support and attack between arguments. We begin by formalising Bipolar frameworks, following which we introduce the notion of a coalition [3]. Such
coalitions can be thought of as the set of all justifications for an argument. Bonds are then a subset of justifications from within a coalition, representing a single line of justifications to the conclusion.

Definition 1. (Bipolar Argument Framework) An abstract bipolar argument framework is a tuple \( BAF = (A, R_{def}, R_{sup}) \) where \( A \) is a set of arguments; \( R_{def} \) is a binary relation \( \subseteq A \times A \) called the defeat relation; \( R_{sup} \) is a binary relation \( \subseteq A \times A \) called the support relation. A bipolar argument framework obeys the constraint that \( R_{def} \cap R_{sup} = \emptyset \).

Definition 2. (Coalitions) Given a bipolar argument framework \( BAF = (A, R_{def}, R_{sup}) \), a coalition is a set of arguments \( C \subseteq A \) such that all of the following conditions hold.
1. The subgraph \( (C, R_{sup} \cap C \times C) \) is connected.
2. \( C \) is conflict free.
3. \( C \) is maximal with respect to set inclusion.

Definition 3. (Bonds) Given a bipolar argument framework \( BAF = (A, R_{def}, R_{sup}) \), and \( C \subseteq A \), a coalition within \( BAF \), a subset \( B \subseteq C \) is a bond if and only if there is no \( a \in C \) such that for some \( b \in B \), \( (b, a) \in R_{sup} \).

Example 2. To illustrate these concepts, consider the bipolar argument framework illustrated in Figure 1. Here, arrows with crosses indicate attacks between arguments, while undecorated arrows represent support. Let us also associate utilities with each argument in the system as follows: \( u(A) = 11 \), \( u(B) = 5 \), \( u(C) = -2 \), \( u(D) = -8 \), \( u(E) = 4 \) and \( u(F) = -10 \).

Figure 2 depicts the two coalitions found in this framework, namely \( C_1 = \{D, A, B, E\} \) and \( C_2 = \{A, D, C, F\} \). The utility associated with the latter is 9, and with the former, 12. Now consider the following bond (which is a subset of \( C_1 \)): \( \{A, E, B\} \). Its utility is 20, and in a dialogue, these are the arguments that an agent should advance.

With the definition of bonds in hand, we now turn our attention to how the maximum utility bond — \( \{A, E, B\} \) in the previous example — can be computed.
3 Identifying Bonds

A naïve approach to computing maximal utility begins with a coalition \( C \) and enumerating its bonds, beginning with arguments which do not support other arguments (these are bonds of cardinality 1), then considering bonds with a single support (i.e. bonds of cardinality 2), and so on. Once all bonds are computed, the maximal utility ones are identified and returned. Clearly, this approach is, in the worst case, exponential in the number of arguments in the domain.

We can construct a polynomial time solution by treating the problem as a maximum flow problem on an appropriate network. The complexity of this type of algorithm is \( O(|C|^3) \), where \( |C| \) is the number of nodes in \( C \) if we apply a push-relabel algorithm [5]. We begin by considering a induced support graph by the coalition over the original graph, defined next. The graphs of Figure 2 are examples of such induced support graphs.

Definition 4. (Induced Support Graph) Let \( BAF = (A, R_{a/f}, R_{s/p}) \) be an abstract bipolar argumentation framework and \( C \subseteq A \) a coalition in \( BAF \). We define the graph \( G^C_{BAF} \) (the induced support graph by \( C \)) as the graph \( G^C_{BAF} = (N_C, E_{s/p}\mid C) \) where:

- Each node in \( N_C \) corresponds to an argument in the coalition \( C \) and
- The edges are only the support edges restricted to the nodes in \( C \) (denoted by \( E_{s/p}\mid C \)).

Within such an induced support graph, a bond is a set \( N_B \subseteq N_C \), where for each \( n \in N_B \), and for each edge \((n, m) \in E_{s/p}\mid C \), it is also the case that \( m \in N_B \). Since we always compute the induced support graph with respect to some underlying bipolar argument framework, we will denote \( G^C_{BAF} \) as \( G^C \).

Additionally, we denote the utility of an argument corresponding to a node \( n \) in the graph as \( u(n) \). The utility of a set \( B \) of arguments is defined as \( u(N_B) = \sum_{n \in N_B} u(n) \). For convenience, we denote those nodes associated with a positive utility by \( N_+^C \), and those with a negative utility by \( N_-^C \).

Fig. 2. Coalitions in Argumentation System in Figure 1
We now show how the problem of finding the maximum utility bond of a coalition can be solved by reducing it to a minimum-cut computation on an extended network $G^C_{\text{extended}}$. The idea is to construct this new network such that a minimum cut will correspond to a maximum utility bond. This idea follows an approach used, for example, in the Project Selection Problem [10].

In order to construct $G^C_{\text{extended}}$ we add a new source $s$ and a new sink $t$ to the graph $G^C$. For each node $n \in N^+_C$ we add an edge $(s, n)$ with capacity $u(n)$. For each node $m \in N^-_C$ we add an edge $(m, t)$ with capacity $-u(m)$ (thus a positive utility). The rest of capacities (the capacities of edges corresponding to those in $G^C$ are set to $\infty$.

**Example 3.** Consider the bipolar argument framework whose graph is shown in Figure 3. The corresponding $G^C_{\text{extended}}$ for the coalition $\{a, b, c, d, e, f\}$ is shown in Figure 4. For readability, we have omitted the "\(\infty\)" label on edges $\{(a, d), (a, e), (b, e), (b, f), (c, f)\}$.

**Theorem 1.** If $(A', B')$ is a minimum cut in $G^C_{\text{extended}}$ then the set $A = A' - \{s\}$ is a maximum utility bond.

**Proof.** The capacity of the cut $\{(s), C \cup \{t\}\}$ is $C = \sum_{n \in N^+_C} u(n)$. So, the maximum flow value in this network is at most $C$.

We want to ensure that if $(A', B')$ is a minimum cut in the graph $G^C_{\text{extended}}$, then $A = A' - \{s\}$ satisfies the bond property (that is, it contains all of the supported elements). Therefore, if the node $i \in A$ has an edge $(i, j)$ in the graph then we must have $j \in A$. Since the capacities of all the edges coming from the graph $G^C$ have capacity $\infty$ this means that we cannot cut along such edge (the flow would be $\infty$).
Therefore, if we compute a minimum cut \((A', B')\) in 
\(G^C_{\text{extended}}\) we have that \(A' - \{s\}\) is a bond. We now prove that it is of maximum utility.

Let us consider any bond \(B\). Let \(A' = B \cup \{s\}\) and \(B' = (C - B) \cup \{t\}\) and consider the cut \((A', B')\).

Since \(B\) is a bond, no edge \((i, j)\) crosses this cut (if not there will be a supported argument not in \(B\)). The capacity of the cut \((A', B')\) satisfying the bond support constraints as defined from \(C\) is \(c(A', B') = C - \sum_{a \in C} u(a)\), where \(C = \sum_{a \in C} u(a)\). We can now prove that the minimum cut in \(G'\) determines the bond of maximum utility. The cuts \((A', B')\) of capacity at most \(C\) are in a one-to-one correspondence with bonds \(A = A' - \{s\}\). The capacity of such a cut is:

\[c(A', B') = C - u(A)\]

The capacity value is a constant, independent of the cut, so the cut with the minimum capacity corresponds to maximum utility bonds.

We have thus proved a polynomial time algorithm for the maximum utility bond decision. While this seems like a strong result, it should be noted that we made use of the fact that our input was a coalition rather than the full argument system. Typically, agents must consider the entire set of arguments and must therefore identify the coalitions themselves. Doing so is an NP-complete problem [3].

To conclude, we discuss the complexity of the two decision problems (bond finding and coalition finding) in an abstract setting, where the input is a bipolar argument framework (as opposed to a compiled knowledge base such as ASPIC+ permits, though this results in an exponential blow-up of the size of the domain).
P1
Input: A bipolar argumentation framework, an utility function and \( k \in \mathbb{Z} \).
Question: Is there a coalition with the utility \( \geq k \).

P2
Input: A bipolar argumentation framework, an utility function and \( k \in \mathbb{Z} \).
Question: Is there a bond with the utility \( \geq k \).

Both problems are NP-complete.

Proof. (Sketch) Clearly, the two problems belongs to NP. To prove the NP-completeness, let us consider an undirected graph \( G \) and a utility function defined on its nodes. If the edges of this graph are considered directed (thus obtaining a digraph that will correspond to the attack digraph), and each non-edge in \( G \) is replaced by a pair of opposed directed support edges, the coalitions in the Bipolar Argumentation Framework obtained are exactly the maximal stables in the initial graph. Indeed, these sets are conflict-free in the Bipolar Argumentation Framework and clearly connected in the support digraph. Thus, deciding if a given undirected graph with weights on its vertices has a maximal stable set of total weight greater or equal than some threshold can be reduced to \( \text{P1} \) (or \( \text{P2} \)). Since this problem is NP-complete [4] we have that \( \text{P1} \) and \( \text{P2} \) are NP-complete.

4 Discussion and Conclusions
In this paper we have introduced the notion of a maximum utility bond. These bonds are related to the justification of arguments when considered in the context of a bipolar argument framework. Since there can be many argument justifications, one needs to identify a heuristic for computing the “best” justification when arguing. We considered a utility based heuristic in which we have assumed that each argument has associated either a positive or a negative numerical utility. Such utility could correspond to the information revealing cost of the argument, or the degree of confidence the agent has in the argument, etc. Furthermore we have assumed that the utility function is additive. We have then described a polynomial time algorithm for computing maximum utility bonds, assuming that coalitions have already been identified.

In the future, we intend to investigate two significant extensions to the current work. First, we have assumed that utilities are additive. However, this simplification is not — in practice — realistic. The presence, or absence, of combinations of arguments could result in very different utilities, such as in the case where revealing some secret information makes other secret information unimportant to keep hidden. To address this case, we can transform our problem into a multi-agent resource allocation (MARA) problem, where arguments are transformed into resources. We must potentially consider an exponentially large input domain (i.e. all possible combinations of arguments), and in [8] such an exponential input was dealt with in the context of coalition formation. We therefore intend to
apply their techniques, noting that additional constraints must be introduced on the technique’s outputs to capture the nature of our domain.

Another potential avenue of future work arises by noting that we have implicitly combined the cost of revealing an argument, and attacks due to the argument on a bond into a single number (the negative utility). In reality, these two values are different; by separating them out, we could perform a minimisation that reflects the different potential preferences of a reasoner.

Abstract
The specification of acceptable behaviour can be achieved via the use of obligations, permissions and prohibitions, collectively known as norms, which identify the states of affairs that should, may, or should not hold. Norms provide the ability to constrain behaviour while preserving individual agent autonomy. While much work has focused on the semantics of norms, the design of normative systems, and in particular understanding the impact of norms on a system, has received little attention. Since norms often interact with each other (for example, a permission may temporarily derogate an obligation, or a prohibition and obligation may conflict), understanding the effects of norms and their interactions becomes increasingly difficult as the number of norms increases. Yet this understanding can be critical in facilitating the design and development of effective or efficient systems. In response, this paper addresses the problem of norm explanation for Naïve users by providing a graphical norm representation that can explicate why a norm is applicable, violated or complied with, and identify the interactions between permissions and other types of norms. We adopt a conceptual graph based semantics to provide this graphical representation while maintaining a formal semantics.

1. Introduction

Solutions to problems arising in the domain of multi-agent systems have often been inspired by approaches from human societies. Nowhere is this more evident than in addressing the problem of controlling the behaviour of agents within open systems. Here, interactions between agents can cause unexpected system behaviour, and traditional procedural approaches fail due to the unpredictability and complexity of these interactions, as well as the inherent autonomy of the agents involved. In human societies, behavioural control is achieved in a declarative manner, by specifying expectations regarding the behaviour of others, such as with laws or rules. These specifications, or norms, identify obligations, permissions and prohibitions that individuals are expected to comply with in particular situations. Drawing on this, there has been much work concerning the application of norms to artificial systems, in which agents are able to make use of concepts such as obligations, permissions, and prohibitions, to represent and reason about socially imposed goals and their execution. Such norm aware agents are able to decide whether to act in a manner consistent with norms, or whether to ignore them. In this context, norms are generally imposed on a set of agents in order to increase the overall utility of a system (often at the cost of individual utility) [18], or to reduce computational or communication overhead [4].

While the design and architecture of norm aware agents is critically important, this is not the only problem that must be addressed when utilising norms. Perhaps more interesting (and more challenging) is the problem of design time identification of which norms are needed in order to achieve some desired behaviour. Norms can interact with each other in unpredictable ways, and determining the effects of a norm on a system can thus be difficult. To identify these problematic norm interactions requires us to be able to explain the effects of a norm, and why, in some specific situation, it is applicable, violated, complied with, or in some other state, yet this has not been investigated to any real depth. Moreover, the ability to provide such explanations can enable designers to better understand the interactions between different norms, thereby allowing them to avoid introducing redundant norms [3], and to specify norms more precisely. Norm explanations can thus provide vital support for the design a normative system. In addition, from the perspective of users, norm explanation can facilitate a more intuitive appreciation of a system by providing a stronger understanding of the reasons why particular norms may have been brought to certain states in response to system events. Such a facility can increase and enhance the trust of a user in relation to operation of the system, providing confidence that it is in fact operating correctly.

Since much of the research into the formal properties of norms has taken place within the area of philosophy and deontic logic...
norms are typically specified within a knowledge-based system (KBS) using a logic which, for non-technical users, is often difficult to understand. However, in order for a KBS to be usable by such users, it is essential that they can understand and control not only the knowledge base construction process, but also how results are obtained from the running system. It should be easy for users not only to enter different pieces of knowledge and to understand their meaning but also to understand the results of the system, and how the system computed these results. This latter aspect, namely the ability to understand why the system gives a certain answer, is especially important since the expertise of different users may vary, and explaining each step of the logical inference process poses a difficult problem.

However, due to the core properties of norms, providing such explanations is not trivial. First, norms can be applicable only in specific circumstances, rather than over a system’s entire lifetime. Thus, examining norms in isolation from a running system may not provide any useful explanation regarding an individual agent’s behaviour. Second, multiple norms can interact with each other, collectively placing complex expectations on the various agents involved. Thus, while it may appear that an agent is violating some obligation, it may actually be the case that the agent is either currently exempt from this obligation due to it not being applicable in the current situation, or due to there being some permission that applies in the current circumstances, overriding the obligation. Given this, it should be clear that it is extremely difficult for non-technical users (indeed, also for technical experts) to interpret a large set of textually (logically) specified norms and identify their effects, and that an alternative solution to norm understanding is required.

In response, our aim in this paper is to provide a sound graphical representation of norms, by adopting a graph-based semantics and applying the semantics to normative systems. To do so, we adopt the normative framework of Oren et al. [17], a generic framework that enables updating and monitoring of the changing status of norms, and supports the normative reasoning process. Now, in order to provide such a graphical representation, we must be able to provide a sound and complete translation between the operations of the normative framework and the operations on the graph-based representation. Not only can this help in understanding the results of an update to the status of a norm, but it also allows for structural optimisations of norms that might not be obvious from the textual (logical) representation of the norm. Each of these is a significant challenge; in this paper, we focus on the former aspect of the graphical representation, leaving the latter for future work.

Oren et al.’s framework represents norms by means of sets of first order logic tuples, which are manipulated using a set of rules that can be reduced to first order logic subsumption on the individual tuple elements. The contribution of this paper is to map norms onto conceptual graphs [19,20], the only graph based formalism to have a sound and complete semantics corresponding to deduction (via subsumption) in first order logic. This formal semantics enables us to easily link Oren et al.’s norms, with their textual representation, to the conceptual graph’s graphical representation, thereby providing a graphical explanation regarding the system’s normative state to non-technical users. This aspect of our work was first discussed in [6], in which it was shown how individual obligations can be represented graphically. Representing permissions, and their interaction with obligations, introduces further complications, but we can extend the basic model to address this, as originally outlined in [16].

The remainder of this paper is structured as follows. In the next section, we provide the necessary formal background to the paper by briefly reviewing the normative framework and introducing the conceptual graph formalism. In Section 3, we show how the status of norms can be computed graphically. Section 4 then considers the graphical representation of interactions between permissions and other norm types. In Section 5, the paper provides a discussion in two parts: first it offers an evaluation of the effectiveness of our approach, together with an assessment of what is needed for more substantial user studies; second, it reviews some important related work. Finally, Section 6 concludes the paper by considering possible extensions to our work.

2. Background

In order to provide the requisite context for the contributions of the paper, and the basis on which we are able to develop norm explanations, we begin in this section by reviewing the formal model of norms. The model focuses on the problem of monitoring in that it facilitates identification of the status of norms as the environment changes over time. We then introduce the graphical formalism used in the remainder of this paper, conceptual graphs (CGs), which we map to the normative model in Section 3. This mapping allows us to address the problem of explanation, identifying why a norm has a particular status at some point in time.

2.1. The normative model

We introduce the normative model in a somewhat informal manner, motivating it in the context of a small example and examining how the model can be applied. Consider a situation in which an agent takes their car to a repair shop in order to be repaired. This repair shop provides a guarantee to its customers that their cars will be repaired within seven days, and thus has an obligation upon it, whenever a car arrives, to repair it within seven days. Clearly, once this obligation is fulfilled, it is lifted, and the repair shop no longer needs to repair the car. However, the obligation remains on the repair shop as long as the car is not repaired (even after seven days have passed). Finally, circumstances beyond the repair shop’s control (for example, a power failure), will give the repair shop permission to repair the car seven days later than otherwise required.

The requirement on the repair shop to mend a car within seven days only obliges the repair shop to take action once a car actually arrives. Until then, the norm is an abstract norm. When a customer brings in a car, the norm is instantiated, thereby obtaining normative force over the repair shop and obliging it to repair the car within seven days. A single abstract norm can result in multiple instantiated norms; if two cars arrive at the repair shop, two instantiations of the abstract norm will occur.

Given this example, we observe that a norm may be defined in terms of five components. First, a norm has a type, such as an obligation, or a permission. Second, a norm has an activation condition, identifying the situations in which the norm affects some agents. Third, a norm imposes some normative condition on the affected agents; if this normative condition does not hold, then the norm is not being complied with (or made use of in the case of a permission). Fourth, norms have an expiration condition, identifying the situations after which the norm no longer affects the agent. Finally, the norm must identify the agents to which it is directed (i.e. those it affects), referred to as the norm targets.

More formally, we assume that the permissions and obligations represented by the norm refer to states and events in some environment, represented by some logical predicate language \( L \), such as first order logic. A norm is then a tuple of the form:

\[
\text{NormType}, \ \text{NormActivation}, \ \text{NormCondition}, \ \text{NormExpiration}, \ \text{NormTarget}
\]
where

1. NormType ∈ {obligation, permission}; and
2. NormActivation, NormCondition, NormExpiration, NormTarget are all well formed formulae (wff) in C.

Thus, for example, the following abstract norm represents the idea that a repair shop must repair a car within seven days of its arrival at the shop1:

\[
\text{(obligation, arrivesAtRepairShop(}X, \text{Car}, T_1), \text{repaired(}Car) \lor (\text{currentTime(}CurrentTime)\land \text{before(}CurrentTime, T_1 + 7\text{days})), \text{repaired(}Car), \text{repairShop(}X)\text{).}
\]

For ease of presentation, we have taken a relaxed approach to the notation, and mixed events and states within this norm, a more consistent approach could be taken, such as the Event Calculus [11], would allow disambiguation of these concepts (as well as providing a richer typology of temporal notions).

If, at any point, an abstract norm’s NormActivation condition holds, an instantiated version of the norm is created (subject to the additional constraint that the norm is not already instantiated for the same reason, as discussed in detail in [17]). The instantiation of a norm involves creating a copy of the abstract norm in which the norm’s variables are bound to the values that caused the NormActivation condition to evaluate to true. When instantiated, the individuals included in NormTarget are identified. These individuals are then either obliged or permitted to bring about the normative goal specified by NormCondition, until such a time as the conditions specified by NormExpiration hold. In this way, instantiated norms persist until they expire. (Note that a more complete logical semantics for the instantiation and processing of norms in this way is provided in [17].)

Now, if a car, car₁, arrives at Bob’s repair shop at time 12, we can instantiate the abstract norm above and obtain the following instantiated norm:

\[
\text{(obligation, arrivesAtRepairShop(}bob, \text{car}_1, 12), \text{repaired(car)} \lor (\text{currentTime(}CurrentTime)\land \text{before(}CurrentTime, 19)), \text{repaired(car), repairShop(}bob)\text{).}
\]

It should be noted that there can be variables within an instantiated norm (as is the case for CurrentTime in the above norm), and that the norm target refers to both the agent (bob), and the role (repairShop) undertaken by the agent in the context of the norm. Given a NormTarget, one simple way of computing the set of agents affected by the norm, is as follows: \(\{X|\text{NormTarget(}role(X))\text{ for any predicate role}\}\).

A key aspect of the normative framework is that it enables the identification of the changing status of norms over time. This status can include the fact that it is instantiated or abstract, whether it is being complied with or violated, and whether it has expired. This is critical in understanding the impact of norms on behaviour and determining what actions to take as a result; the work in [17] introduces several distinct predicates that capture these different possibilities for status. For example, violation of a norm may require some remedial action, and is thus a relevant status value, with an associated predicate. Importantly, the status can also be referred to by other norms. For example, a norm stating that “if a car has not been repaired after seven days, the repair must be free”, can be represented as follows (assuming that the norm above is labelled n₁):

\[
\text{(obligation, violated(}n_1)\text{, repairCost(}Car, 0)\text{, false, repairShop(}X)\text{).}
\]

Here, the violated(\(n_1\)) predicate refers to the norm’s status, and evaluates to true if and only if \(n_1\) is an instantiated obligation whose normative condition evaluates to false, and for which there is no permission that allows the negation of the normative condition. This, and other such predicates are formally defined in [17].

As seen in this example, norms can explicitly refer to other norms and the variables found within them (such as Car in the example above). In addition, as we will see later there may also be implicit references to other norms (most notably in the case of permissions). Determining the status of any particular norm thus requires an examination of the interactions between multiple norms; when a system contains many norms connected to each other by such implicit and explicit references, it can be extremely difficult to identify precisely why some norm has a particular associated status. In order to address this difficulty of understanding and identification, we seek an alternative means of examining the status of norms in such systems. In particular, since humans find it much easier to assimilate large amounts of graphical information, as opposed to information in other forms, it is appropriate to make use of a graphical model to represent and visualise norms. In doing so, we are able to make explicit the links between the norms described above in a way that is amenable to human inspection and understanding. Of course, since such a representation must also to be able to be processed by machine, the best choice of representation to use for this purpose is one that is humanly readable, and computationally tractable” (cf. [20]). Throughout the remainder of this paper we use the term

---

1 Unless otherwise stated, we make use of Prolug notation within our logical formulae. More specifically, variables are written with an initial capital letter, while constants begin with a lowercase letter.
"conceptual graphs" to denote the family of formalisms rooted in Sowa's work and then enriched and further developed with a graph-based approach (cf. [5]).

In the conceptual graph (CG) approach, all kinds of knowledge can be encoded as graphs and can thus be naturally visualised. More specifically, a CG partitions knowledge into two types, the first of which identifies the CG's vocabulary, and can be seen as a basic ontology, and the second of which, (referred to as the basic graph) stores facts encoded using the CG's vocabulary. The vocabulary, referred to as the CG's support, is composed of two distinct parts, namely a partial order of concepts, and a partial order of relations (of any arity). Since both parts of the support are partial orders, they can be visualised by their Hasse diagram, where the partial order represents a specialisation relation, \( r \leq t \), indicates that \( r \) is a specialisation of \( t \). More specifically, if \( r \) and \( t \) are concepts, \( r \leq t \) indicates that every instance of the concept \( r \) is also an instance of the concept \( t \). Fig. 1 provides an example of a concept hierarchy constructed in this way, and which is used in the illustrative example throughout this paper. Similarly, if \( r \) and \( t \) are relations, and these relations have the same arity, say \( k \), then \( r \leq t \) means that if \( r \) holds between \( k \) entities, then also holds between these \( k \) entities. Fig. 2 shows the relation hierarchy that is used in the example throughout this paper. These relations are organised by arity — unary, binary and ternary and so on — with a separate graph for each.

Now, a CG's basic graph encodes knowledge based on the representation of entities and their relationships. This encoding takes the form of a bipartite graph, consisting of concept nodes that represent entities, and relation nodes that represent relationships between these entities or their properties. A concept node is labelled by a pair, \( t;m \), where \( t \) is a concept drawn from the concept hierarchy, and \( m \) is called the marker of the node. Markers consist of either a specific individual name, or a marker, denoted \( * \), which acts as a generic marker, and is used if the concept node refers to an unspecified entity. A relation node is labelled by a relation \( r \) taken from the relation hierarchy and, if \( r \) has an arity of \( k \), the relation node must be incidental to \( k \) totally ordered edges. Classically, concept nodes are drawn as rectangles and relation nodes as ovals.

The order on edges incidental to a \( k \)-ary relation node is then represented by labelling the edges with numbers from 1 to \( k \). Fig. 3 provides an example of a basic graph that expresses the fact that a vehicle arrived at the RepairShop at a certain Time. Finally, since the notion of instantiated norm is central to our framework, we occasionally refer to an instantiated basic graph, which is simply a basic graph with no generic markers, as shown in Fig. 4.

Given these basic notions of conceptual graphs, a mapping between a CG and first order logic can be used to provide the CG with a semantics. This mapping, denoted by \( \Phi \) in the conceptual graphs literature, utilises a first order language corresponding to the elements of the conceptual graph's vocabulary (i.e. its relation and concept hierarchies). Elements from the concept hierarchy are translated into unary predicates, and elements from the relation hierarchy with an arity of \( k \) are mapped into \( k \)-ary predicates. Individual names are then constants in the logic. Formulae are added to the logic based on the partial orders of concepts and relations: if \( r \) and \( t \) are concepts, and \( r \leq t \), then the formula \( \forall x (\Phi(t(x)) \rightarrow \Phi(r(x))) \) is obtained. Similarly, if \( r \) and \( r' \) are \( k \)-ary relations, with \( r \leq r' \), then the formula \( \forall x_1 \ldots x_k (\Phi(r(x_1, \ldots, x_k)) \rightarrow \Phi(r'(x_1, \ldots, x_k))) \) is obtained. A fact \( G \) obtained from the basic graph can then be translated into a positive, conjunctive and existentially closed formula (via the mapping \( \Phi(G) \)), with each concept node being translated into a variable or a constant. If the concept node is a generic node (as in the concept nodes on the left hand side of Fig. 3), then \( \Phi(G) \) results in a variable, otherwise \( \Phi(G) \) returns the concept node's individual marker.

While we have shown how CGs can be mapped to a first order logic formula, mapping between CGs and first order logic in order to perform reasoning is cumbersome, and a large part of the power of the CG approach is obtained from the ability to perform reasoning over the graphs themselves. The fundamental operation used to perform such reasoning is projection. In order to describe this concept, we must first define the notion of a homomorphism.

Let \( G \) and \( H \) be two basic graphs (BGs). A homomorphism \( m \), from \( G \) to \( H \), is a mapping, from the concept node set of \( G \) to the concept node set of \( H \), and from the relation node set of \( G \) to the relation node set of \( H \), that preserves edges and may decrease concept and relation labels. That is:

- for any edge labelled \( i \) between the concept node \( c \) and relation node \( r \) in \( G \), there is an edge labelled \( i \) between the nodes \( \pi(c) \) and \( \pi(r) \) in \( H \); and
- for any (concept or relation) node \( x \) in \( G \), the label of its image \( \pi(x) \) in \( H \) is a specialisation of the label of \( x \); that is, \( \pi(x) \subseteq x \).

Homomorphisms are used to form projections between two BGs, as illustrated in Fig. 5. Here, the BG on the left hand side of the figure models the situations when some Car arrives at bob’s repair shop at Time 12, while the right hand side of the figure models the case when some Vehicle arrives at some RepairShop at some Time. The homomorphism (indicated using dashed lines) indicates that node RepairShop on the right can be mapped onto the

---

**Fig. 1.** Conceptual graph support: the concept hierarchy.
RepairShop node on the left with marker bob, that the Vehicle node on the right can be mapped to Car on the left, and that the generic Time node on the right can be mapped to a specific Time node. Finally, the arrivesAtRepairShop relation maps between the two BGs.

Now, an important theorem in the CG literature (referred to as the fundamental theorem) also allows us to map back from first order logic to conceptual graphs. This theorem states that, given two BGs, G and H, there is a homomorphism from G to H if and only if \( \Phi(G) \) is a semantic consequence of \( \Phi(H) \) and the logical translation of the vocabulary: \( \Phi(x), \Phi(y) \rightarrow \Phi(G) \). This is a soundness and completeness theorem of BG homomorphism with respect to first order logic entailment, the consequence of which is that a homomorphism between two graphs is, in effect, an explanation as to why logical subsumption takes place. Since such homomorphisms can be represented graphically, this allows for visual representations of logical subsumption, the explanation of which is a unique feature of CGs. Any alternative logic-based graphical representation language would have to include an additional separate explanation layer as well as the representation layer itself.

Given the fundamental building blocks we have now introduced, of the normative model and conceptual graphs, we can proceed to detail how a norm can be represented within a CG-based framework.

### 3. Graphically computing the status of norms

#### 3.1. Modelling norms with CGs

By encoding structured knowledge graphically, CGs can provide a way to represent, illustrate and interpret the states through which norms proceed; that is, whether they have been activated, violated, fulfilled, or expired. Then, by connecting such representations (or depictions) of permissions and obligations, it is possible to interpret whether an obligation has truly been violated, or whether a permission derogates this obligation under particular circumstances.

One commonly encountered problem is that norms can sometimes be fulfilled by multiple different actions, events or states. Intuitively, if these conditions are separated by disjunctions, they can be evaluated in a tree-like structure by the norm reasoner. We make this explicit by representing norms in such a structure, with every level of the tree corresponding to one type of condition in the norm. Moreover, at every level, we break the condition into a disjunction of positive first order logic conjunctions. This representation ensures that normative reasoning is sound and complete with respect to a particular kind of path-finding in the norm tree (finding at least one satisfied level node). Now, when instantiated, a norm’s activation condition becomes fixed, and its normative and expiration conditions are used to determine its status. This suggests that the tree structure is indeed suitable for use in representing a norm. In what follows, we proceed to define this tree structure, which we refer to as a norm tree.
A norm tree represents both abstract and instantiated norms. Its root is associated with the entire norm (more specifically, its type and target), while the remaining levels represent different parts of the norm. (For this purpose, we also assume that a norm's target is a conjunctive formula, and can thus be represented as a conceptual graph). Nodes in the second level are associated with the activation condition, nodes in the third level are associated with the normative condition, and nodes in the fourth level with the expiration condition. Each of the nodes within the tree has an associated CG representation of its content, as illustrated in Fig. 6.

Given this basic structure, different branches of the norm tree can be used to represent disjunctive conditions within a specific norm attribute. Thus, for example, a norm with a normative condition of the form \( a \_ b \) would have two branches at the norm tree's third level. As indicated above, we assume that the norm target parameter consists of a conjunctive combination of predicates (in other words, a norm is associated with a specific group of individuals rather than applying to some subgroup or another), and that all other parameters (except for norm type), may contain disjunctions. In this way, in order to represent the norm as a norm tree, we transform all of its attributes into disjunctive normal form, to get a norm represented as follows:

\[
\langle Type, \bigvee_{i=1}^{a} AC_i, \bigvee_{j=1}^{c} NC_j, \bigvee_{k=1}^{e} EC_k, NT \rangle.
\]  

(1)

where \( AC, NC, EC, \) and \( NT \) are all conjunctive first order formulae so that, for example, \( AC = \bigvee_{i=1}^{a} AC_i \). Furthermore, by assuming negation as failure, we can ensure that all of these formulae are positive (by introducing an explicit predicate for negation), and can therefore represent each as a conceptual graph, defined on some given support (i.e. the domain ontology).

Given a norm \( N \) in disjunctive normal form as in Eq. (1) above, we define its norm tree as a tree for which each node contains a norm and is labelled by a CG as follows.

1. The root node of the tree contains norm \( N \) and is labelled by a CG identifying the norm’s type and targets (i.e. Type and NT).
2. The root node has \( a \) child nodes (i.e. nodes at level one) where, for \( i = 1 \ldots a \), child node \( i \) is labelled with the CG representing \( AC_i \) and contains a norm \( N_i \) of the form:

\[
\langle Type, AC_i, \bigvee_{j=1}^{c} NC_j, \bigvee_{k=1}^{e} EC_k, NT \rangle.
\]

3. Each node at level two, which is a child of \( N_i \), and is labelled with a CG representing \( NC_j \), contains a norm \( N_{ij} \) for \( j = 1 \ldots c \) of the form:

\[
\langle Type, AC_i, NC_j, \bigvee_{k=1}^{e} EC_k, NT \rangle.
\]

4. Each node at level three, which is a child of \( N_{ij} \), and is labelled with a CG representing \( EC_k \), contains a norm \( N_{ijk} \) for \( k = 1 \ldots e \) of the form:

\[
\langle Type, AC_i, NC_j, EC_k, NT \rangle.
\]
3.2. Modelling norms in the repair domain

Consider the norm of our car repair example, which obliges a repair shop to repair a car within seven days of its arrival. The left hand side of Fig. 7 illustrates the norm tree associated with this norm. For simplicity, we have ignored the norm target parameter, assuming that it is present in the root node. The dotted line between the nodes and CGs identifies which nodes are labelled with which CGs. It should be noted that the function relation, found in the right hand normative condition node, is used to compute whether the current time is greater than seven days from the time the car arrived for repair. This is used to simplify the CG shown in the figure; within a complete system, this CG would make use of an arithmetic function to add seven days to the car’s arrival time, and then make use of an additional function or predicate to compare the current time to the deadline to determine whether the car has been repaired in time. Now again consider the nodes at the third level of the norm tree. These correspond to the norm condition and, when translated to first order logic, yield a formula of the form repaired(Car) ∨ function(CurrentTime, Time * 7 days).

Note that there is a separation between the semantics of the normative model and its norms, and the semantics of the knowledge-based system. For a parameter (such as the normative condition) in the norm to evaluate to true, any of the disjunctions from which it is composed must evaluate to true (e.g. repaired(Car) in the above example). This aspect of a norm is captured by the normative model’s semantics, and is thus represented by the norm tree structure. However, reasoning within the knowledge-based system is kept separate from the norm model semantics by means of conceptual graph annotations of the nodes in the normative tree. Thus, the knowledge-based system identifies which of the normative condition’s disjunctions actually evaluated to true in the case where the normative condition is true. A user of the system could then be presented with the explanation of why the norm condition is valid: in the context of the repair shop norm, at least one node is satisfied (or both). While the figures in this paper are monochrome, colour can be added to a running system in order to identify the validity of a node (for example, red could mean invalid, while green could mean valid).

Finally, the right hand side of Fig. 7 illustrates the norm tree for the permission (to repair a car later than 7 days if there is a power failure) found in our example. Since no disjunctions exist within the activation, expiration and normative conditions, the norm tree has no branches.

This conceptual graph representation provides us with two advantages over a textual representation of the norm. First, the conceptual graph representation makes the types of concepts linked by predicates visually explicit (for example, RepairShop: as opposed to X). While this problem is easily addressed by manually changing the variable names of the textual logic representation (using meaningful literals), the heuristic employed could be confusing. Second, and more importantly, for elaborated pieces of knowledge (namely conjunctions with common variables) the translation between natural language and logical formulae becomes very difficult. For example, suppose that we are trying to represent the fact that a car arrives at a Volvo repair shop, that the repair shop accepts only cars of the same make, that the time at which the car arrives at the repair shop must be later than 9, and that this is the opening time of the repair shop. While the conceptual graph depiction is intuitive given its visual nature, the logic-based (textual) approach can be difficult to follow.

3.3. Instantiating norms

Now, consider the abstract norm illustrated on the left hand side of Fig. 7, and suppose that a new fact—that some car, c1, arrived at the repair shop belonging to bob at time 12—is added to the knowledge base. In predicate form, we write arrivesAtRepairShop(bob, c1, 12). This piece of knowledge is projected to all the norm conditions in the system in the following way. Using projection, the fact is mapped onto the abstract norm of Fig. 7, and a new norm tree, with the appropriate CG nodes now labelled by constants, is created. This CG is shown in Fig. 8 in which, for clarity, nodes in the norm tree belonging to an abstract norm are depicted in white (c.f. Fig. 7).

It should be noted that there can be multiple instantiated versions of the same abstract norm simultaneously. However, each of these will have a different set of variable bindings, and thus a different CG associated with the norm tree.

3.4. Computing the status of norms

So far, we have shown how abstract and instantiated norms may be represented as norm trees, but we have not yet considered how to determine the status of a norm using our norm tree structure. Consider the left hand side of Fig. 8, which represents the instantiated norm from the repair shop example. The right hand side of the figure shows the CG representation of the environment.

Fig. 7. The norm tree for the abstract obligation norm (left) and abstract permission norm (right) found in the repair shop example.
as stored within the knowledge base. This CG represents the fact that a car $c_1$ arrived at the repair shop at time 12. To distinguish between abstract and instantiated norms, we colour the nodes of an instantiated norm using different colours (which are always non-white), as opposed to white abstract norms.

Now, as new facts appear and disappear within the knowledge base, the status of norms also changes. Determining this status may be achieved by checking for the existence of projections between the facts in the environment and the conceptual graph annotations of the norm tree. Fig. 9 illustrates the situation when an additional fact—namely that the current time is before time 19—is added to the environment (represented by the two CGs on the right of the figure). The norm tree on the left of Fig. 9 now contains a mixture of black and grey nodes. A grey node corresponds to the fact that the node is satisfied; that is, there is a projection between the environment and the corresponding CG annotation. The remaining nodes are black: they are not satisfied. Thus, in Fig. 9, illustrating the car repair example, there is no projection between the CG node representing the expiration condition, which states that the car is repaired, and the CG on the right of Fig. 9. Similarly, there is a projection (and thus the node is grey) between the CG on the right, and the CG linked to the node at the normative condition level stating that the current time is before 19 (the condition in this latter node is represented by the function taking in the datatype, time and current time). If, at some later point, the car is repaired, the black nodes within the norm tree will turn grey.

During its lifecycle, an abstract norm becomes instantiated. While instantiated, its normative condition may evaluate to true or false at different times. Eventually, the norm's expiration condition evaluates to true, after which the instantiated norm is deleted. We have already seen how one may determine whether a norm may be instantiated using a norm tree. A norm's normative condition is satisfied (that is, it evaluates to true), if any of the nodes at the norm condition level are grey. Similarly, a norm expires if any of the nodes at the expiration condition level are grey.

A norm's status includes whether it is activated or expiring, and whether it is being satisfied, and it is trivial to determine this from the norm tree. It is also possible to determine more sophisticated aspects providing a richer notion of the status of a norm from a norm tree. As an example, in the next section, we discuss how to determine whether an obligation has been violated. All aspects of the status of a norm can be computed by posing queries to the knowledge base, and thus, it is possible to visually determine the status of a norm.

4. Computing violation with permissions

One critical aspect of normative state that cannot be computed directly form a norm tree is whether the norm is violated. This is because of the way in which we treat permissions. In [2], Boella and van der Torre point out that permissions can be viewed as exceptions to obligations and prohibitions, and this is how
permissions are handled by our model. Thus, for example, given an obligation on the repair shop to repair a car within 7 days, a permission to instead repair the car within 14 days derogates the obligation. While the obligation may not be complied with (because the car may not be repaired within 7 days), the repair shop will not be in violation of the obligation unless 14 days have expired.

Permissions thus do not exist in isolation, but instead act as exceptions to other types of norms. This means that in evaluating whether an obligation or prohibition is violated, one must consider not only the possibly violated norm itself, but also the permissions present. However, given a large normative system, identifying the appropriate permission that may prevent a violation from occurring can be challenging. Our visual approach can help overcome the cognitive load imposed by this problem by highlighting any relevant permissions that prevent a norm from being violated.

To illustrate, we return to our car repair example. If a power failure occurred at time 14, then the (instantiated) permission allowing Bob to repair car c₁ within 14 days (i.e. by day 28) is as follows:

(permission. powerFailure(bob, 14). ¬repaired(c₁). currentTime(CurrentTime) ∧ before(CurrentTime, 28days). repairShop(bob)).

Conceptually, in order to determine whether an instantiated and un-expired permission derogates an obligation or prohibition, we must check whether the permission’s norm condition is consistent with the obligation. If it is not consistent, in the sense that the permission allows the negation of the obligation, then derogation takes place, otherwise the permission does not affect the obligation. In our example, ¬repaired(c₁) is inconsistent when evaluated against repaired(c₁), and the permission thus derogates the obligation. This check for consistency thus lies at the heart of our work.

Clearly, consistency checking requires the ability to represent and reason about the negation of a relation. However, the standard CG formalism is unable to represent such negated relations, and we make use of an extension to CGs first proposed by Mugnier and Leclère [15] to show how the consistency check can be performed from within the CG formalism. Mugnier and Leclère introduce the idea of a negative relation node which, when present as a node in a CG, identifies the fact that the named relation does not exist between the concepts incident on the node. Now, the approach we adopt here makes use of the closed world assumption, and extends a CG to include its negative relation nodes. More specifically, we add all possible negative relation nodes that do not make the graph contradictory to the CG’s basic graph. Thus, for example, if we do not know that a car has been repaired, we now explicitly state that it has not been repaired; if a node repaired(car₁) is not present in some CG, the completed form of the CG must include the node ¬repaired(car₁).

Given this completed CG, if the permission’s normative condition cannot be projected into the CG (because the car has in fact been repaired, for example), the permission derogates the obligation (or rather, that node in the norm tree for which the CG projection is unsuccessful, which will not be coloured black). The permission, and the relevant concepts and relations that derogate the permission, can then be displayed to the user to explain why the norm is not in violation. If, on the other hand, the permission is not relevant to the obligation, then a violation occurs, and the violated norm can again be highlighted in order to show the user its status. Thus, given a norm tree for an (instantiated, unexpired) obligation N, the norm it represents is violated if and only if all of its nodes at the normative condition level are coloured black.

Fig. 10 illustrates the derogation of an obligation by a permission. Dashed lines indicate links between the concepts and relations found in the two nodes, and the normative condition node marked with a grey node with a black centre in the obligation indicates that the node, while evaluating to false, is derogated by a permission. From the figure, it is clear that the obligation is not violated. Note that the permission’s activation condition node is black. We assume that while a power failure occurred in the past (instantiating the permission), there is currently no power failure.

4.1 Case study

To illustrate the overall framework, we consider an additional scenario in which rapid response medical units must perform some duties when an emergency situation occurs. These units have the following obligation:

“If a state of emergency has been declared, a rescue unit is obliged to travel to a casualty, and then collect them, or provide them with medicine until they have no more space and are out of medicines”.

![Permission and Obligation](image-url)

Fig. 10. A norm tree for a permission (left), and obligation (right) evaluated according to some knowledge, showing how the permission derogates the obligation.
Formally, this obligation is represented as follows:

\[
\text{obligation; stateOfEmergency(\cdot) \land casualty(\cdot), travel(U, C) \land (collect(U, C) \lor medicate(U, C)), noSpace(U) \land noMedicine(U), rescueUnit(U)).}
\]

The disjunctive normal form of the obligation's normative condition is:

\[
(\text{travel(U, C) \land collect(U, C) \lor (travel(U, C) \land medicate(U, C))}).
\]

Given this, we assume a very simple permission representing casualty triage: "If the casualty is dead, there is no need to medicate them". Formally, this is as follows:

\[
\text{permission; dead(C), \neg medicate(U, C), false, rescueUnit(U)).}
\]

In order to construct the norm tree, we begin by identifying the concepts and relations found in this scenario, where the concepts include StateOfEmergency, Casualty, RescueUnit, and Dead, and the relations include travel, collect, medicate, noSpace, and noMedicine. These concepts and relations yield the support displayed in Fig. 11, and the abstract norms illustrated in Fig. 12.

Now, suppose that a state of emergency exists, and that a dead casualty c1 has been detected by a rescue unit r1. Furthermore, r1 has space and medicine available. Given that the rescue unit has not travelled to the casualty, collected it, or provided medicine, is it in violation of its obligation? In order to determine this, we must compute the completed CG of the instantiated obligation's normative condition. Fig. 13 shows the completed form of the graph for both the left and right hand branches of the instantiated obligation norm tree's normative condition nodes. The dotted lines within Fig. 13 illustrate that the permission's normative condition projects into the obligation's right hand branch normative condition.
However, no such projection is possible into the left hand branch. Therefore, the permission derogates the left hand branch of the obligation’s norm condition, and the norm is not violated. This is shown in Fig. 14. In summary, our CG approach to norm explanation makes clear exactly how the permission enables a user to understand how the permission interacts with the obligation.

5. Discussion

5.1. Evaluation

Norms provide a means of regulating system behaviour, yet their structure and operation can often obscure the understanding that is possible, especially by end-users. In particular, it is important to understand not just the structure of norms, but also their status at different points in time, and the ways in which they interact. This latter aspect is critical, for the interaction between norms can affect their status. In order to provide an effective means for supporting user understanding, we have developed a visual model to explain the structure and status of a norm. This ability to provide explanations of a norm’s status is especially useful; for example, complex contract disputes may require that some rewards or penalties be assigned by a human mediator, but in order to perform this assignment, the mediator must first understand which norms were violated, and which were complied with. Norm explanation is also important at the system design stage, where an understanding of norm status in different situations is needed to ensure correct system behaviour.

Previous work such as [5] has demonstrated that graphical systems excel in cases where non-technical users must be catered for, and this is exactly the approach we adopt. More specifically, we can identify the following benefits of our graphical normative representation. First, the graphical system can be used to identify which elements of the environment impact on a norm, even when making use of specialisation or generalisation of concepts or relations (as illustrated in Fig. 5), when it is not clear to a user how different concepts may relate to each other. In this way, users can directly track the effects of changes in the environment on a norm. Similarly, through the association of CGs with norms, it is possible to support navigation between norms sharing identical, specialised or generalised relations or nodes, or sharing markers. The set of norms affected by changes to the environment can thus be easily tracked.

Importantly, a graphical system is able to provide the user with an easily understandable snapshot regarding the status of the system. More specifically, by adopting an approach in which the colours associated with the nodes of an instantiated norm’s tree indicate their status, we provide a means for users to quickly identify which norms have what status, and why (as illustrated in Fig. 9).

Finally, and as indicated above, the interactions between different parts of a system can be made explicit. Since individual norms can combine in complex ways to give sophisticated structures by virtue of the links between permissions and obligations, for example, providing a visual representation can be argued to be vital to ensure clarity of presentation and understanding. Indeed, identifying obligations that are derogated due to permissions, and in turn identifying these permissions is not trivial, yet as we have shown in Section 4 (and Fig. 10), this becomes relatively straightforward with an appropriate representation.
All these aspects can be seen directly from the work presented in this paper. Clearly however, while this evaluation of our contribution is justified in its own terms, and demonstrates the validity of our approach in providing explanation, the claim of aiding users requires a more substantial (and more challenging) evaluation. In particular, since one of the core advantages of the graphical approach lies in enhancing user understanding, the next step in evaluating our framework must be to undertake user studies, comparing the graphical approach and standard, text-based techniques for representing norms, and their impact on and value to users. Current work is concerned with implementation of a software tool for exactly this purpose, providing clear visualisations of the status of norms as described earlier by displaying the norm trees found in a running system, colouring tree nodes as appropriate, displaying the node CG graphs (and enabling further analysis to identify and display projections, graph support and the like). More interesting and valuable functionalities are also anticipated, for example, if an obligation is derogated, selecting an appropriate node will allow a user to visualise the associated derogating permission, and vice versa.

Although anecdotal evidence from early trials with users already suggests that our approach has significant merit, this more substantial user evaluation will require over time an understanding of norm status in different situations is needed to explain why and when norms were violated, and which were complied with. Norm explanation is also important at the system design stage, where an understanding of a norm's status in such domains is particularly useful. To perform this assignment, the mediator must first understand which norms were violated, and which were complied with. Rewards or penalties be assigned by a human mediator, but in our approach lie in enhancing user understanding to end-users. Our underlying norm formalism is able to model the norm's lifecycle, while our conceptual graph based representation enables a user to consider the interactions between obligations and permissions, and understand them in an intuitive manner. Many avenues remain open for future investigation. Other studies have shown that graphical representations are more easily understood than logic-based ones [5] by non-experts, and though we have proceed on this legitimate assumption, we have yet to undertake the user studies that will confirm this empirically, but aim to do so in the short term. We also intend to leverage the formal power of our model, by investigating the use of graph theoretical operations to identify redundant norms [2]. Similarly, we believe that graph-based operations can be used to detect, and help resolve, normative conflict. Both of these applications effectively validate the structure of the norms, and we thus aim to apply existing work on CG validation [8] to aid us in this task. Furthermore, projection can also act as a similarity measure, and can thus be applied to determining the trustworthiness of contracts (as encoded by groups of norms) along the lines suggested by Groth et al. [10]. Finally, we have focused on the status of norms represented will transform into the evolved object in a predictable manner, and can therefore not be directly applied to our work. Nevertheless, identifying a more formal approach to creating instantiated norms from abstract norms is worth pursuing, as this would allow us to answer questions about possible norm instantiations.

Our graphical representation highlights the link between permissions and obligations, and borrows some ideas from [7], wherein CGs were used to express and manage the interdependencies between security policy rules. Since norms can be used to express rules [12], many issues identified there (such as the detection of redundant policies) map directly to the domain of norms. More generally, however, we are aware of very little work dealing with the explanation of norms to users. This may be due to an implicit assumption that normative systems are fully automated, and that explanation is thus not necessary, or perhaps due to an assumption regarding the technical expertise of a system's users. However, even if a user is able to understand a norm representation, graphic explanations may still be advantageous when reasoning about complex interactions between large groups of norms. One exception to this is the recent work of Miles et al. [14], which touches on the concept of norm explanation. Here, a graph is used to analyse and explain norm violation, and then to identify whether there were mitigating circumstances for the violation.

6. Conclusions and future work

Norms have a complex lifecycle, becoming instantiated, and thus placing an expectation on an agent's behaviour at certain points in time, following which they may expire and cease to influence an agent. Within a long lived system, norms may be instantiated and expire multiple times; at any point in time, only a certain subset of norms may be relevant to identifying what behaviour should take place. Furthermore, examining a single norm in isolation does not provide enough information to determine whether an agent is acting in compliance with the norm. For example, as shown in Section 4, permissions may derogate norms, and multiple norms must be considered when reasoning about their effects. Critically, while existing norm representations are sufficient for automated reasoning, their form is not ideal for explaining the behaviour of the system to end-users. In order to provide a user with an effective understanding of a normative system, all of these issues must be taken into consideration.

The goal of our approach is to provide an effective tool for system understanding to end-users. Our underlying norm formalism is able to model the norm's lifecycle, while our conceptual graph based representation enables a user to consider the interactions between obligations and permissions, and understand them in an intuitive manner. Many avenues remain open for future investigation. Other studies have shown that graphical representations are more easily understood than logic-based ones [5] by non-experts, and though we have proceed on this legitimate assumption, we have yet to undertake the user studies that will confirm this empirically, but aim to do so in the short term. We also intend to leverage the formal power of our model, by investigating the use of graph theoretical operations to identify redundant norms [2]. Similarly, we believe that graph-based operations can be used to detect, and help resolve, normative conflict. Both of these applications effectively validate the structure of the norms, and we thus aim to apply existing work on CG validation [8] to aid us in this task. Furthermore, projection can also act as a similarity measure, and can thus be applied to determining the trustworthiness of contracts (as encoded by groups of norms) along the lines suggested by Groth et al. [10]. Finally, we have focused on the status of norms...
at a single point in time; we plan to investigate how our approach can aid in explaining interactions not only between simultaneously active norms, but also how they can be used to identify and explain temporally distributed normative interactions.

ABSTRACT
The classical setting of query answering either assumes the existence of just one knowledge requester, or the knowledge requests from different parties are treated independently from each other. This assumption does not always hold in practical applications where requesters often are in direct competition for knowledge. We propose a formal model for this type of scenario by introducing the Multi-Agent Knowledge Allocation (MAKA) setting which combines the fields of query answering in information systems and multi-agent resource allocation.

1. INTRODUCTION
Conjunctive query answering (between a knowledge requester and a knowledge provider) constitutes the de-facto standard of interacting with resources of structured information: databases or ontological information systems. The classical setting in query answering is focused on the case where just one knowledge requester is present. In case multiple requesters are present, the queries posed by different parties are processed and answered as independent from each other, thus making the multi-requester scenario a straightforward extension of the individual case. While the above practice is natural in some cases, the assumption that queries can be processed independently clearly does not always hold in practical applications where the requesters are in direct competition for information. Let us consider for instance a knowledge provider (example scenarios include military applications, news agencies, intelligence services, etc.). Of course, in this context, requester agents will not be willing to share “sensitive” information with other agents.

2. QUERYING WITH EXCLUSIVITY CONSTRAINTS
In [3] we fully introduce our framework of exclusivity-aware querying as a basis for the MAKA bidding formalism. In the following, we will just provide an intuitive overview of this work by the means of an example. Consider the following predicates: actor, director, singer (all unary), marriage and act (binary) and five constants AJ (Angelina Jolie), BP (Brad Pitt), MMS (Ms. and Ms. Smith), JB (Jessica Biel), JT (Justin Timberlake). A knowledge base consists of ground facts such as:

\[
\text{actor}(\text{AJ}) \quad \text{director}(\text{AJ}) \quad \text{marriage}(\text{AJ}, \text{BP})
\]

\[
\text{actor}(\text{BP}) \quad \text{singer}(\text{JT}) \quad \text{act}(\text{AJ}, \text{MMS})
\]

actor(JB) act(BP, MMS)

If we consider a set of variables \( V = \{x, y\} \) and the set of constants \( C = \{\text{AJ}, \text{BP}, \text{MMS}, \text{JB}, \text{JT}\} \), then \( \text{actor}(x), \text{act}(y, \text{MMS}) \), marriage(\text{AJ}, \text{BP}) are all atoms over the sets \( P \) and \( C \).

Since in the MAKA scenario, requesters might be competing for certain pieces of knowledge, we have to provide them with the possibility of asking for an atom exclusively (exclusive) or not (shared). This additional information is captured by the notion of exclusivity-annotated atoms, ground facts and queries.

Some exclusivity-annotated atoms would for instance be: (actor(x), x), (marriage(\text{AJ}, \text{BP}), excl) etc.

Note that the idea of exclusivity annotation is a novel concept going beyond the classical query answering framework. We assume an order exclusive \( \succeq \) shared being used for query answering. It allows to specify concisely that an answer delivered exclusively is
suitable for a knowledge requester who demanded that information shared (but not vice versa).

For example, a query asking exclusively for marriages between actors and directors (where only the “marriage” itself is required as exclusive information, but the “actor” and “director” knowledge is sharable with other knowledge requester agents) is:

\[
\text{(marriage}(x,y), \text{exclusive}) \land (\langle \text{actor}(x), \text{shared} \rangle \lor \langle \text{director}(y), \text{shared} \rangle).
\]

There is only one answer to this query w.r.t. our previously introduced knowledge base: \( \mu = \{x \mapsto \text{AJ}, y \mapsto \text{BP}\} \). This means that marriage(AJ, BP) can only be exclusively allocated (as marriage(AJ, BP, exclusive)) but the director(AJ) and actor(BP) atoms can be either “shareably” allocated with other requesters (\( \langle \text{actor}( BP), \text{shared} \rangle \) or exclusively allocated only to one requester agent (\( \langle \text{director}(AJ), \text{exclusive} \rangle \)).

3. THE KNOWLEDGE ALLOCATION PROBLEM DEFINED

Multi Agent Knowledge Allocation (MAKA) can be interpreted as an abstraction of a market-based centralized distributed knowledge-based system for query answering. In such a MAKA system, there is central node \( n \), the auctioneer (or the knowledge provider), and a set of \( n \) nodes, \( J = \{1, \ldots, n\} \), the bidders (or the knowledge requesters), which express their information need (including exclusivity requirements) via queries, which are to be evaluated against a knowledge base \( K \), held by the auctioneer.

The auctioneer asks bidders to submit in a specified common language, the bidding language, their knowledge request: \( (q, \varphi) \) where \( q \) is an exclusivity-annotated query and \( \varphi : \mathbb{N} \rightarrow \mathbb{R}_+ \) is a valuation function.

Following the ongoing example in the paper, a knowledge request for an exclusively known marriage between a known actor and a known director, where each such marriage information is paid 30 units for would be the singleton set \( \{ (q, \varphi) \} \) with

\[
q = \langle \text{marriage}(x,y), \text{exclusive} \rangle \land (\langle \text{actor}(x), \text{shared} \rangle \lor \langle \text{director}(y), \text{shared} \rangle)\ 
\]

\[
\varphi = k \rightarrow 30 - k.
\]

The valuation function \( \varphi : \mathbb{N} \rightarrow \mathbb{R}_+ \) can be defined in several ways. Assuming that val\(_i\) \( u_i \in \mathbb{R}_+ \) denotes a bidder \( i \)'s interest to obtain a single answer to a query \( q \), standard valuation options are:

- naive valuation: \( \varphi^s([S]) = |S| \cdot \text{val}_i \),
- threshold valuation: \( \varphi^t([S]) = |S| \cdot \text{val}_i \) if \( |S| \leq \text{threshold}_i \), and \( |S| \cdot \text{val}_i - \text{discount}_i \) otherwise,
- budget valuation: \( \varphi^b([S]) = \min\{\varphi^s([S]), \text{budget}_i\} \) where \( \varphi^s \) can either be \( \varphi^t \) or \( \varphi^b \).

Based on bidders’ valuations, the auctioneer will determine a knowledge allocation, specifying for each bidder her obtained knowledge bundle and satisfying the exclusivity constraints (expressing that exclusivity annotations associated to atoms in the respective bundle are indeed complied with).

Given a knowledge base and a set of \( n \) bidders, a knowledge allocation is an \( n \)-tuple of subsets of the exclusivity-enriched knowledge base (i.e., the knowledge base atoms annotated with both exclusive and shared). An allocation needs to satisfy two conditions: First, we cannot allocate the same atom as both shared and exclusive. Second, an exclusive atom can only be allocated to one agent.

Given a knowledge allocation, one can compute its global value by summing up the individual prizes paid by the bidders for the share they receive. Obviously, the knowledge allocation problem aims at an optimal allocation, which maximizes this value. Please see [3] providing more details and a full formalisation of the above intuitions, as well as a network representation of the problem, such that the winner determination can be cast into a max flow problem on the proposed graph structure.

4. CONCLUSION AND FUTURE WORK

We have introduced the problem of Multi-Agent Knowledge Allocation by drawing from the fields of query answering in information systems and combinatorial auctions. To this end, we have sketched a bidding language based on exclusivity-annotated conjunctive queries. This approach opens up interesting work directions such as:

- Extending the bidding language: One straightforward extension would be to allow not just for ground facts (like marriage(AJ, BP)) to be delivered to the requester but also for “anonymized” facts (like marriage(AJ, *) or, more formally \( \exists x. \text{marriage}(AJ, x) \)), which require handling adaption.
- Extending knowledge base expressivity: On one hand, the knowledge base formalism could be extended to cover not just ground facts but more advanced logical schemas such as Datalog rules (used in deductive databases) or ontology languages. In that case, a distinction has to be made between propositions which are explicitly present in the knowledge base and those entailed by it.
- Covering Dynamic Aspects of Knowledge Allocation: In particular in the area of news, dynamic aspects are of paramount importance: news items are annotated by time stamps and their value usually greatly depends on their timeliness. Moreover we can assume the information provider’s knowledge pool to be continuously updated by incoming streams of new information.
- Multiple Providers: Finally, it might be useful to extend the setting to the case where multiple agents offer knowledge; in that case different auctioning and allocation mechanisms would have to be considered. This would also widen the focus towards distributed querying as well as knowledge-providing web-services.

Abstract—The amount of data available greatly increases every year and information can be quite valuable in the right hands. The existing mechanisms for selling goods, such as VCG, cannot handle sharable goods, such as information. To alleviate this limitation we present our preliminary work on mechanisms for selling goods that can be shared or copied. We present and analyze efficient incentive compatible mechanisms for selling a single sharable good to bidders who are happy to share it.

I. INTRODUCTION

The evolution of the Web, and thus the facility of sharing data and putting data online has greatly improved, at least in the last decade. The data deluge can be noted in many day to day use cases: electronic journals access, music sharing, videos, social networks, open data initiatives etc. In the knowledge representation community (in a broad sense, and mainly in the database community) it is implicitly assumed that every answer to a query will be simply allocated to the user (unless constrained due to privacy restrictions); not to mention that the multiplicity of knowledge requesters was simply regarded as a simple extension of the individual case. However, in today’s Web (Web of Data, Web of Science, Web of Knowledge, Semantic Web, Web 2.0 etc) information being given freely clearly does not always hold in practical applications where the requesters are in direct competition for information. The bottom line is that data, seen as an allocatable good, has the property of high cost production but negligible cost to copy. Studying implications of pricing information and allocating it thus becomes highly timely [1], [2]. The pricing information question on the web has also been investigated from a Linked Data perspective where information markets are being created [3], [4], [5].

A very important issue is that data can easily be shared (for example, music or software). If we were to apply well known auction mechanisms (e.g. VCG) to selling pieces of information that can be shared, hence are infinitely copied, no profit would be made; this would happen because competition is what drives the prices up [6] and offering more items - here infinite - than buyers essentially removes any competition in this setting. And yet getting profit is usually the first goal of a seller. Now, [7] examines expanding auctions where more copies of the same good are offered as the competition increases. However, their mechanism does not handle infinite copies and it is likely not incentive compatible (IC), meaning that bidder would have an incentive to lie which would break down the mechanism. For this reason, it is important to propose IC mechanisms for this problem. Some mechanisms have been proposed in [8], [9] but they analyze the mechanisms from a worse case viewpoint. As shown by [3] this is not always relevant in practice where the distributions are not always a-priori known. Taking inspirations from these algorithm in this paper we present and analyze several incentive compatible mechanisms for selling a single sharable good to bidders who are happy to share it, aiming at creating competition by restricting the number of winners.

The only related work the examines this problem is [9]. However, this work is only concerned with examining the performance of the proposed mechanisms in the worst case, meaning how poor the performance becomes for any input even if this poor performance only occurs for extremely unlikely input. For a practical application, what would interest a company or an individual selling the information is the expected revenue that can be obtained from each mechanism. In view of this, in this paper, we thoroughly study mechanisms for selling goods that can be shared or copied as many times as necessary. We further the analysis of incentive compatible mechanisms, characterize a whole family of such mechanisms that can be used and evaluate the revenue obtained and the efficiency of these mechanisms, comparing also against the mechanisms of [9], showing that our mechanisms are better in average performance in most cases.

II. INCENTIVE COMPATIBLE MECHANISMS

In this section, we present formally the setting that we will address in this paper. We then present several incentive compatible mechanisms, starting from two baseline ones (mechanism $M_{k+1}$ and $M_0$) and then characterizing a family of such mechanisms, which generalizes the basic mechanism $M_{k+1}$. We subsequently evaluate these mechanisms in Section III.

We consider a set of $n$ bidders who want shared access to a piece of information. The valuations of the bidders who want shared access are $V = \{v_1, \ldots, v_n\}$.

Now, the good could be also allocated to all the buyers but in this case we would not be able to extract any profit. For example, if we apply the well known VCG mechanism to this setting, the goods will be sold to all the buyers at a price equal to 0, thus making no money at all! This essentially happens because offering more items than buyers essentially removes any competition which would drive the prices up. There is a couple of straightforward ways to deal with this issue:

- One is restricting the number of winners. If the number of winners is fixed to a number $k$ which is less than the actual number $n$ of interested buyers, then this immediately

\footnote{This is a very basic and straightforward mechanism and a variation of this has been presented in [9].}
will create competition between the bidders. By running an \((n_0 + 1)^{th}\) price auction (with \(n_0 = b\)), henceforth denoted as mechanism \(M^{b+1}\), we can guarantee that this is IC and provides some profit while ensuring that the bidders will all pay the same price.

- Another is setting a reserve price. Instead of fixing the number of winners, a reserve price \(r\) is set; any bidder with valuation higher than \(r\) will bid the good. Now, the only IC mechanism in this instance is to make every winner pay \(r\), henceforth denoted as mechanism \(M^r\); otherwise if the price paid depends on their bids, these bidders (who have valuations higher than \(r\)) will bid \(r + \epsilon, \epsilon > 0\) instead, as they know that any bid above \(r\) will guarantee that they win.

A serious shortcoming of both these mechanisms (\(M^{b+1}\) and \(M^r\)) is that the number of winners and the reserve price, respectively, should be selected optimally beforehand in order to maximize the revenue of the seller. This would need to rely on information such as prior knowledge of the distribution of the valuations. It cannot depend on the actual bidders valuations as then the mechanism would not be IC.

To alleviate this shortcoming, we need to design a mechanism that chooses the number of winners and subsequently the price that they pay so as to maximize the total revenue of the seller. Essentially, we should maximize \(\max _{i \in \{1,\ldots,n\}} j_i^{(j)}\) where \(j_i^{(j)}\) are the valuations of \(\mathcal{V}\) ordered from highest to lowest. A first attempt would be to select \(j\) as to maximize \(\max _{i \in \{1,\ldots,n\}} j_i^{(j+1)}\) instead and the price paid by the winners would be equal to \(j_i^{(j+1)}\), the top bid that did not win. This is essentially the main idea from both the Vickrey (i.e. second price) auction [10] and the VCG mechanism. However, in this case this mechanism is not IC. The bidders can manipulate the price that they pay, and whether they win or not, by submitting a bid which is not their true value thus changing the number of winners.

### Example 1: Assume valuations \(\mathcal{V} = \{11,9,7,5,3\}\).

- For bidder 1: \(\mathcal{V}^1 = \{9,7,5,3\}\), therefore \(j^* = 3\) and since \(v_1 = 11 \geq 5 = v_3\) she wins with payment 5.
- For bidder 2: \(\mathcal{V}^2 = \{11,7,5,3\}\), therefore \(j^* = 3\) and since \(v_2 = 9 \geq 5 = v_3\) wins with payment 5.
- For bidder 3: \(\mathcal{V}^3 = \{11,9,5,3\}\), thus \(j^* = 2\) and since \(v_3 = 7 < 9 = v_5\) she does not win.
- For bidder 4: \(\mathcal{V}^4 = \{11,9,7,3\}\), therefore \(j^* = 3\) and since \(v_1 = 11 \geq 7 = v_5\) she wins at payment 5.
- Bidder 5 (the bidder with the lowest valuation) can never win in this mechanism.

Therefore the two bidders with the highest valuations will win at a payment equal to the fourth highest bid of 5.

### Example 2: Assume valuations \(\mathcal{V} = \{10,10,7,7,7.5\}\).

- For bidders 1 and 2: \(\mathcal{V}^1 = \{10,10,7,7,7.5\}\), therefore \(j^* = 4\) and since \(v_1 = 10 \geq 7 = v_3\) they win with payment 7.
- For bidder 3 (as well as 4 and 5): \(\mathcal{V}^3 = \{10,10,7,7.5\}\), therefore \(j^* = 4\) and since \(v_3 = 7 \geq 7 = v_5\) they win at payment 7.
- Bidder 6 does not win.

Therefore the five bidders with the highest valuations will win at a payment equal to the fifth highest bid of 7.

Now, notice that had we been able to use all the information available the optimal allocation in Example 2 would have been to sell the good to the top three bidders at a price equal to 5. However, the third bidder is not a winner meaning that some efficiency has been lost. On the other hand, in Example 3, bidders 3, 4 and 5 pay their valuation. It makes sense to examine the properties of this mechanism, regarding which of the bidders win and the price that they pay. We will use the following lemma:

\[ \text{Definition 1 (IC Revenue Maximizing Mechanism } M^A) : \]

For each bidder \(i \in \{1,\ldots,n\}\) do:

- If \(i > 1\) and \(v_i^{(j)} = v_i^{(j-1)}\) then

\[ \text{decision is same as bidder with valuation } v_i^{(j-1)}. \]

Else

- Compute \(j^* = \arg \max j_i^{(j)}\)\(^2\)

- Compute \(j_i^{(j)}\) such that \(j_i^{(j)} = \mathcal{V}^i\) without the valuation \(v_i\).

- If \(v_i < j_i^{(j)}\), then the bidder with value \(v_i\) does not win:

\[ \text{otherwise, she is a winner and pays } v_i^{(j)} \]

\[ \text{Theorem 1: Mechanism } M^A \text{ is IC.} \]

As a variation of this mechanism has been presented in [9] and it is easy to prove that it is IC we will not do so here. What we will focus on are the properties of this mechanism as they have not been analyzed in previous work and they will be useful both in the experimental analysis we will conduct, as well as in generalizing it to the family of mechanisms we will later present.

We give two examples of how this mechanism works, the second of which contains tied valuations:

### Example 2: Assume valuations \(\mathcal{V} = \{11,9,7,5,3\}\).

- For bidder 1: \(\mathcal{V}^1 = \{9,7,5,3\}\), therefore \(j^* = 3\) and since \(v_1 = 11 \geq 5 = v_3\) she wins with payment 5.
- For bidder 2: \(\mathcal{V}^2 = \{11,7,5,3\}\), therefore \(j^* = 3\) and since \(v_2 = 9 \geq 5 = v_3\) she wins with payment 5.
- For bidder 3: \(\mathcal{V}^3 = \{11,9,5,3\}\), thus \(j^* = 2\) and since \(v_3 = 7 < 9 = v_5\) she does not win.
- For bidder 4: \(\mathcal{V}^4 = \{11,9,7,3\}\), therefore \(j^* = 3\) and since \(v_1 = 11 \geq 7 = v_5\) she wins at payment 5.
- Bidder 5 (the bidder with the lowest valuation) can never win in this mechanism.

Therefore the two bidders with the highest valuations will win at a payment equal to the fourth highest bid of 5.

### Example 3: Assume valuations \(\mathcal{V} = \{10,10,7,7,7.5\}\).

- For bidders 1 (and 2): \(\mathcal{V}^1 = \{10,10,7,7,7.5\}\), therefore \(j^* = 4\) and since \(v_1 = 10 \geq 7 = v_3\) they win with payment 7.
- For bidder 3 (as well as 4 and 5): \(\mathcal{V}^3 = \{10,10,7,7.5\}\), therefore \(j^* = 4\) and since \(v_3 = 7 \geq 7 = v_5\) they win at payment 7.
- Bidder 6 does not win.

Therefore the five bidders with the highest valuations will win at a payment equal to the fifth highest bid of 7.

\[^2\text{In case that } \arg \max \text{ is a set, we define it to return the maximum element, meaning that if } \exists j_1 < j_2 \text{ where } j_1v_i^{(j_1)} = j_2v_i^{(j_2)} \text{ are the maximizing terms, then } \arg \max \text{ will return } j_2 \text{ and similarly if there are more maximizing terms.}\]
Lemma 1: If the \( i \)th term is the maximizing one for the optimization problem solved by mechanism \( M^4 \), when it disregards bidder \( i \)'s bid, then it is also the maximizing term when the bid of bidder \( i' \) is \( i + 1 \) is disregarded. Furthermore, if the maximizing term is instead the \( j \)th one (where \( j \neq i \)), when disregarding bidder \( i \)'s bid, then either it remains the maximizing term, when disregarding bidder \( i' \)'s bid (\( i' = i + 1 \)), or the new \( i \)th term is the maximizing one.

Proof: Due to space this proof as well as the proofs of the following theorem are omitted. They can be found in our technical report available at http://hal.inria.fr/lirmm-00830805/.

We obtain the following theorem:

Theorem 2: When using mechanism \( M^4 \) some number \( j' \) of the top bidders will win, where \( j' \leq j' + 1 \) and \( j' = \arg \max_j j v^{j+1} \). The price that they all pay is equal to \( v^{j'+1} \). Furthermore \( j' \leq j \); when there are no ties in the bidders’ valuations.

We can observe that this mechanism has some very desirable properties beyond being simply IC: firstly, all the winners pay the same price, so there can be no envy really among them, and, secondly, they pay the price \( v^{j'+1} \) that is the one that maximizes the profit of the seller. However, in order for the profit of the seller and the efficiency of the system to be maximized it should be that \( j' = (j'+1) \) bidders should win at this price. To alleviate this weakness of mechanism \( M^4 \), we will examine some variations of it, eventually generalizing it to a whole family of mechanisms. Essentially, the maximization step \( j^* = \arg \max_j j v^j \) is replaced by a voting protocol.

First, notice that the desired optimization \( \max_{j \in \{1, \ldots, n\}} j v^j \) and the maximization step \( j^* = \arg \max_j j v^j \) of mechanism \( M^4 \) are the same optimization problem when bidder \( i \) is the one with the highest valuation (her valuation is ranked first). In other cases though, they can lead to different results and this is the reason for the inefficiency. We cannot use any knowledge of the bidder’s value when deciding whether a winner or not even the rank (i.e. how many other bidders have a higher valuation). Therefore, we propose to examine all possible cases for the rank of the valuation of bidder \( i \) and then aggregate the “optimal” number of winners in each case via a voting protocol.

To illustrate what we mean we re-examine the setting of Example 2.

Example 4: Assume valuations \( \bar{v} = \{9, 7, 5, 3\} \).

- For bidder 1, it is \( \bar{v}_1 = \{9, 7, 5, 3\} \). For her valuation we can assume the following cases:
  1) \( v_1 \geq 9 \). Then the set of valuations is \( \{v_1, 9, 7, 5, 3\} \), and it would be optimal to have 3 winners.
  2) \( 9 > v_1 \geq 7 \). Similarly 3 winners is the optimal.
  3) \( 7 > v_1 \geq 5 \). Similarly 3 winners is the optimal.
  4) \( 5 > v_1 \geq 3 \). Then the set of valuations is \( \{9, 7, 5, v_1, 3\} \), and it would be optimal to either have 3 (when \( v_1 \geq 4 \)) or 4 (when \( v_1 < 4 \)) winners. Only in the second subcase would bidder 1 win.
  5) \( v_1 < 3 \). Then the whole set of valuations would be \( \{9, 7, 5, 3, v_1\} \), and it would be optimal to have 4 (when \( v_1 \geq 2.5 \)) or 2 (when \( v_1 < 2.5 \)) winners. In either case bidder 1 would not be selected as a winner.

- For bidder 2, we obtain similar results as for bidder 1.

- For bidder 3: \( \bar{v}_3 = \{11, 9, 5, 3\} \). For her valuation we can assume the following cases:
  1) \( v_3 \geq 11 \). Then the set of valuations is \( \{v_3, 11, 9, 5, 3\} \), and it would be optimal to have 2 winners.
  2) \( 11 > v_3 \geq 9 \). Similarly 2 winners is the optimal.
  3) \( 9 > v_3 \geq 7 \). Then the whole set of valuations would be \( \{11, 9, v_3, 5, 3\} \), and it would be optimal to have 2 (when \( v_3 \geq 7.5 \)) or 3 (when \( v_3 < 7.5 \)) winners. Only in the second subcase would bidder 3 win.
  4) \( 5 > v_3 \geq 3 \). Then the whole set of valuations would be \( \{11, 9, 5, v_3, 3\} \), and it would be optimal to either have 3 (when \( v_3 \geq 4 \)) or 4 (when \( v_3 < 4 \)) winners. Only in the second subcase would bidder 3 win.
  5) \( v_3 < 3 \). Then the whole set of valuations would be \( \{11, 9, 5, 3, v_3\} \), and it would be optimal to either have 4 (when \( v_1 \geq 2.5 \)) or 2 (when \( v_1 < 2.5 \)) winners. In either case bidder 3 would not be selected as a winner.

- For bidder 4: \( \bar{v}_4 = \{11, 9, 7, 3\} \). For her valuation we can assume the following cases:
  1) \( v_4 \geq 11 \). Then the set of valuations is \( \{v_4, 11, 9, 7, 3\} \), and it would be optimal to have 3 winners.
  2) \( 11 > v_4 \geq 9 \). Similarly 3 winners is the optimal.
  3) \( 9 > v_4 \geq 7 \). Similarly 3 winners is the optimal.
  4) \( 7 > v_4 \geq 5 \). Then the whole set of valuations would be \( \{11, 9, 7, v_4, 3\} \), and it would be optimal to either have 3 (when \( v_4 \geq 14/3 \)) or 2 (when \( v_4 < 14/3 \)) winners.
  5) \( v_4 < 3 \). Then the whole set of valuations would be \( \{11, 9, 7, 5, v_4\} \), and it would be optimal to either have 4 (when \( v_1 \geq 2.5 \)) or 2 (when \( v_1 < 2.5 \)) winners.

- Bidder 5 (the bidder with the lowest valuation) can never win (unless there is a tie which we choose not to consider when designing our mechanisms, as it happens with very low probability), therefore we do not analyze her case.

What can we observe from this example? Examining what happens each time we tried to solve the optimization problem for each bidder, the optimal number of winners changes as the valuation of that bidder is assumed to various ranges of values; of course the knowledge of this value is ignored in order to keep the mechanism IC, this is the reason why we need to examine all these possible cases. Now, note that considering only the case when this value is assumed to be higher than the highest among the remaining valuations and basing the decision on only that case, gives mechanism \( M^4 \). However, this does not use the information from all the other cases where the bidder examined might still be a winner. Thus, we propose to use a voting protocol where, for each case where the bidder examined is selected to be a winner, votes would be cast for the number of winners that maximize the total profit.

We see that the decision regarding each bidders depends on the cases examined. Thus, we generalize the previous mechanism to consider all cases examined. To this end, we
propose the following family of mechanisms $\mathcal{M}^*$ where each case (i.e., when the rank of the missing valuation is $k$) casts votes with weight $w_k$:

**Definition 2 (Family of IC Mechanisms $\mathcal{M}^*(\tilde{w}, \delta)$):**

Select the function $\delta <\text{profit} >, <\max\text{-profit}>$

For each bidder $i \in \{1, \ldots, n\}$ do:

1. If $i > 1$ and $v^{(i)} < v^{(i-1)}$ then decision is same as bidder with valuation $v^{(i-1)}$.

Else

2. Set $\tilde{w}$, as $\tilde{w}$ without the valuation $v^{(i)}$.

Set $\psi_k = 0, \forall k = 1, \ldots, n$

For $k = 1, \ldots, n - 1$ do

Assume that the missing valuation (denoted $v_i$) is $v^{(k)} \geq v^{(k)} > v^{(k)}$, where $v^{(k)} = \infty$ & $v^{(k)} = 0$

Set the weight $w_k$ for

Define the terms $t_i = \{(l-1)v^{(l)}; l < k,\}

$t_i = \{(l-1)v^{(l)}; l \geq k,\}$

$t_i = \{(l-1)v^{(l)}; l \geq k,\}$

$t_i = \{(l-1)v^{(l)}; l \geq k,\}$

$t_i = \{(l-1)v^{(l)}; l \geq k,\}$

Among these terms, find the highest: $l_i$ and the second highest: $l_2$

The min and max values of term $(k-1)v_i$ are resp.:

$t_{\min} = (k-1)v^{(l_i)}, t_{\max} = (k-1)v^{(l_i)}$

If $l_i \geq t_{\max}$ and $l_i \geq k$ then

$\psi_k = \psi_k + \psi_i$ (full vote for best - weighted)

If $l_2 \geq t_{\max}$ and $l_2 \geq k$ then

$\psi_k = \psi_k + \psi_i(\text{partial vote for } k\text{th highest})$

If $l_i > t_{\max}$ and $l_2 \geq k$ then

$\psi_k = \psi_k + \psi_i$ (full vote for best - weighted)

If $l_i \geq t_{\max}$ and $l_2 \geq k$ then

$\psi_k = \psi_k + \psi_i(\text{partial vote for } k\text{th highest})$

Select $j^* = \arg \max \psi_k$

If $v^{(i)} < v^{(j^*)}$, bidder with value $v^{(i)}$ does not win otherwise, she is a winner and pays $w_j$.

The two lines of arguments in bold define the parameters that characterize the whole range of mechanisms that belong to this family of mechanisms $\mathcal{M}^*$. For example, mechanism $\mathcal{M}^*$, which we presented earlier, is derived from $\mathcal{M}^*$, by setting $\delta = 0, w_1 = 1$ and $w_2 = 0, \forall k > 1$. In this paper we will also use in our experiments, the following two mechanisms which are derived from $\mathcal{M}^*$:

- mechanism $\mathcal{M}^V_\infty$, in which $\delta(x,y) = \frac{x}{y}$ and $w_k = 1, \forall k$
- mechanism $\mathcal{M}^W_\infty$, in which $\delta(x,y) = \frac{x}{y}$ and $w_k = 1, \forall k = (n - 2)\frac{v^{(k-1)}}{v^{(i-1)} - v^{(i-1)}}, \forall k > 1$

In both these mechanisms, the best option gets 1 vote while the second best option (regarding the number of winners) gets votes equal to the ratio of the second highest and the highest profits. However, in the first mechanism, the weights for all cases are 1, while in the second the votes are weighted depending on how likely each case $v^{(k-1)} \geq v^{(k)} > v^{(k)}$ is, which depends on the distance between the values $v^{(k-1)}$ and $v^{(k)}$.

---

*The original algorithm which did not impose this restriction had much worse performance, and it would always perform worse than the other algorithms, therefore it does not provide a good enough benchmark without this (minor) modification, as this significantly improves the mechanism’s performance.*

---

**III. EXPERIMENTAL EVALUATION**

In this section, we conduct experiments to evaluate the performance of the mechanisms we presented in the previous section. Our goal is to compare the seller revenue and the efficiency (i.e., the sum of the valuations of all winners) of the different mechanisms $\mathcal{M}^V, \mathcal{M}^M$ and $\mathcal{M}^R$ as opposed to using the baseline mechanisms $\mathcal{M}^4+1$ and $\mathcal{M}^R$. We will also compare them with the Parameterized Random Sampling Optimal Price auction (RSOP$_i^P$) presented in Section 6.1 of [9]; we have implemented an improvement of this mechanism which does not allow one of the two randomized sets to be empty and

![Fig. 4. Revenue and efficiency of mechanisms $\mathcal{M}^4+1$ and $\mathcal{M}^R$ as the number of winners $k$ and the reserve price $R$ varies (versus those of $\mathcal{M}^V$). The number of bidder $n = 10$.](image-url)
we assume knowledge of the distribution in order to select the optimal value of the parameter $r$ for this mechanism. In the experiments we call this mechanism $M^P$ (i.e. probabilistic). Note that in [9], another algorithm is proposed for this problem: the Random Sampling Profit Extraction auction (RSPE); however the performance of this mechanism is very poor as it sacrifices half the profit (in most cases), therefore we chose not to include it in our experiments.

Now, there is very little research and knowledge on what real distributions of the valuations for data are like. Some information on current data markets is given in [3], however very little is known about the expected performance of the different mechanisms. In view of this, we present here three sets of experiments each performed with a different valuation distribution. We explain why we select each, in turn, before presenting the results of the simulation.

**Experiment Set 1:** We simulate $n$ bidders whose valuations are i.i.d. random variables drawn from the uniform distribution on $[1, \ldots, 100]$. The number of bidders $n$ varies from 3 to 20. For the baseline mechanisms $M^{k+1}$ and $M^R$, we calculate beforehand the best values for $k$ and $R$ respectively that maximize the expected revenue using the knowledge of the distribution from which the bids are drawn; for the other mechanisms no such knowledge is necessary.

The results of these experiments are presented in the table of Figure 1. The best revenue among the mechanisms $M^A$, $M^V$ and $M^W$ (of family $M^*$) is consistently obtained by mechanism $M^W$. Its revenue is actually better than that of mechanism $M^{k+1}$ (with $k$ set optimally to maximize revenue), because mechanism $M^W$ adjusts the number of winners based on the actual bids submitted rather than choosing the same number regardless of the input. On the other hand, mechanism $M^R$ (with $R$ set optimally) clearly outperforms the other mechanisms, because it uses its knowledge of the expected valuations to set a threshold (a reserve price) which must be paid by all winning bidders. In this way it balances the revenue from each winner against the number of bidders. However, this mechanism is very dependent on knowing the distribution of valuations, as setting the reserve $R$ to the wrong value will reduce very significantly the revenue obtained. In fact, to examine this effect we present in Figure 4, the revenue and efficiency of mechanisms $M^{k+1}$ and $M^R$ for different values of $k$ and $R$ respectively. We observe that the revenue obtained from $M^R$ degrades significantly if $R$ deviates by more than 15 from its optimal value. What is worse, if mistakenly the valuations were assumed to be between 1 and 50 (or, even worse, between 1 and 200), which would have approximately

---

</table>
halved (or doubled resp.) the value for \( R \), then very little revenue would be obtained!

Regarding the efficiency of the mechanisms, we observe that all of them perform similarly. The only exception is mechanism \( M^A_1 \), because, as we’ve seen in Example 2, sometimes the mechanism reduces the number of winners which significantly impacts its efficiency.

Finally, we notice that mechanism \( M^P \) performs worst than any other mechanism (even \( M^{k+1} \) in many cases). This happens because the mechanism splits the problem into two separate problems and uses the solution (i.e. the best price) of one to impose the cutoff price for the other; however, the solutions for these two problems are not always very close (or identical which would be the optimal case) and this leads to a loss of revenue and some efficiency.

**Experiment Set 2:** In the previous experiment set, we assumed that the valuations could take a continuum of values. The extreme opposite of this is that only two values are possible, thus we assume here that the values have a 50% chance of being either 1 or 10. While we do not believe that this could be realistic (to have so small a number of possible values), this case is suggested in [9] as the case when the deterministic algorithms would fail to produce good results.

The results of these experiments are presented in the table of Figure 2. We observe that the performance of the baseline mechanisms is similar in broad terms to the previous experiment set. Regarding the other mechanisms, now mechanism \( M^A \) performs best, better than mechanisms \( M^P \) and \( M^W \). This is not entirely surprising as the possible values are only two, which means that in almost all cases the optimal decision would be to select the bidder with value 10 and make them pay 10, which matches the maximum profit that can ever be extracted from any (not necessarily IC) mechanism; the other more complex mechanisms \( M^V \) and \( M^W \) try to be cleverer, but that is unnecessary and they suffer a bit because of this.

Furthermore, mechanism \( M^P \) actually shines in this case, even if it is outperformed by mechanism \( M^A \), because of having only two possible values, and the solutions for the two problems solved by the mechanism are almost always identical, therefore this leads to almost maximal revenue and efficiency.

**Experiment Set 3:** We mentioned that the second distribution is probably not realistic for real data markets. However, this does pose the question what happens in an intermediate case, where there are relatively few possible values (but still not as few as only two). To this end, we assumed for the third experiment set we conducted, that the values have a 10% chance of being 55, 60, 65, . . . , 95, 100 (10 possible values in total).

The results of these experiments are presented in the table of Figure 3. In this case, we notice that the observations of the different mechanisms performance are close to those made for the first experiment set. In particular, disregarding the baseline mechanisms, mechanism \( M^W \) performs best in this set closely followed by mechanism \( M^V \). Mechanism \( M^P \) lacks in performance to a substantial degree (the exception being when the number of bidders \( n \) approaches 20) and so does mechanism \( M^A \).

To summarize our observations from all the experiment sets, we notice that the baseline mechanism \( M^A \) is overall consistently the best, but it relies significantly on selecting the best reserve \( R \). Our proposed mechanisms (and in particular \( M^W \) and \( M^V \)) are typically the best among the other mechanisms. The exception to this is when there are very few (two or close) possible valuations when it is more advantageous to use mechanisms \( M^A \) primarily and \( M^P \) secondary. However, we remind the reader that mechanism \( M^P \) also relies on using knowledge of the valuation distribution in order to select the optimal parameter \( r \), albeit to a lesser extent than mechanism \( M^P \).

**IV. CONCLUSIONS**

In this paper, we studied mechanisms for selling sharable information goods. We presented and analyzed several IC mechanisms, including a family of such mechanisms, for selling a single sharable good to bidders who are happy to share it; furthermore, we analyzed the properties of these mechanisms via simulations (for the most part).

There are still a number of avenues for future work. The most important extension is to examine whether we can generalize our mechanisms to the case where several goods are sold to bidder who want to buy bundles of these and are willing to share or would want each good exclusively. Furthermore, for the single unit case examined in this paper, the mechanisms of family \( M^A \) restrict the number of winners, in a similar manner to mechanism \( M^{k+1} \); the difference being not using prior knowledge; in this spirit, our second extension will examine new mechanisms that estimate a reserve price (like \( M^D \), the highest revenue mechanism we considered) without using prior knowledge about the valuation distribution.

What Can Argumentation Do for Inconsistent Ontology Query Answering?

–Technical Report–

Madalina Croitoru1, Srdjan Vesic2*

1INRIA, LIRMM, Univ. Montpellier 2, France; 2CRIL - CNRS, France

Abstract. The area of inconsistent ontological knowledge base query answering studies the problem of inferring from an inconsistent ontology. To deal with such a situation, different semantics have been defined in the literature (e.g. AR, IAR, ICR). Argumentation theory can also be used to draw conclusions under inconsistency. Given a set of arguments and attacks between them, one applies a particular semantics (e.g. stable, preferred, grounded) to calculate the sets of accepted arguments and conclusions. However, it is not clear what are the similarities and differences of semantics from ontological knowledge base query answering and semantics from argumentation theory. This paper provides the answer to that question. Namely, we prove that: (1) sceptical acceptance under stable and preferred semantics corresponds to ICR semantics; (2) universal acceptance under stable and preferred semantics corresponds to AR semantics; (3) acceptance under grounded semantics corresponds to IAR semantics. We also prove that the argumentation framework we define satisfies the rationality postulates (e.g. consistency, closure).

1 Introduction

Ontological knowledge base query answering problem has received renewed interest in the knowledge representation community (and especially in the Semantic Web domain where it is known as the ontology based data access problem [17]). It considers a consistent ontological knowledge base (made from facts and rules) and aims to answer if a query is entailed by the knowledge base (KB). Recently, this question was also considered in the case where the KB is inconsistent [16, 8]. Maximal consistent subsets of the KB, called repairs, are then considered and different semantics (based on classical entailment on repairs) are proposed in order to compute the set of accepted formulae.

Argumentation theory is also a well-known method for dealing with inconsistent knowledge [5, 2]. Logic-based argumentation [6] considers constructing arguments from

* The major part of the work on this paper was carried out while Srdjan Vesic was affiliated with the Computer Science and Communication Research Unit at the University of Luxembourg. During this period, Srdjan Vesic’s project was supported by the National Research Fund, Luxembourg, and cofunded under the Marie Curie Actions of the European Commission (FP7- COFUND). At the time when the authors were finishing the work on this paper, Srdjan Vesic was a CRIL researcher affiliated with CRIL.
inconsistent knowledge bases, identifying attacks between them and selecting acceptable arguments and their conclusions. In order to know which arguments to accept, one applies a particular argumentation semantics.

This paper starts from the observation that both inconsistent ontological KB query answering and instantiated argumentation theory deal with the same issue, which is reasoning under inconsistent information. Furthermore, both communities have several mechanisms to select acceptable conclusions and they both call them semantics. The research questions one could immediately ask are: Is there a link between the semantics used in inconsistent ontological KB query answering and those from argumentation theory? Is it possible to instantiate Dung’s ([15]) abstract argumentation theory in a way to implement the existing semantics from ontological KB query answering? If so, which semantics from ontological KB query answering correspond to which semantics from argumentation theory? Does the proposed instantiation of Dung’s abstract argumentation theory satisfy the rationality postulates [10]?

There are several benefits from answering those questions. First, it would allow to import some results from argumentation theory to ontological query answering and vice versa, and more generally open the way to the Argumentation Web [19]. Second, it might be possible to use these results in order to explain to users how repairs are constructed and why a particular conclusion holds in a given semantics by constructing and evaluating arguments in favour of different conclusions [14]. Also, on a more theoretical side, proving a link between argumentation theory and the results in the knowledge representation community would be a step forward in understanding the expressibility of Dung’s abstract theory for logic based argumentation [21].

The paper is organised as follows. In Section 2 the ontological query answering problem is explained and the logical language used throughout the paper is introduced. The end of this section introduces the existing semantics proposed in the literature to deal with inconsistent knowledge bases. Then, in Section 3, we define the basics of argumentation theory. Section 4 proves the links between the extensions obtained under different argumentation semantics in this instantiated logical argumentation setting and the repairs of the ontological knowledge base. We show the equivalence between the semantics from inconsistent ontological KB query answering area and those defined in argumentation theory in Section 5. Furthermore, the argumentation framework thus defined respects the rationality postulates (Section 6). The paper concludes with Section 7.

2 Ontological Conjunctive Query Answering

The main goal of section is to introduce the syntax and semantics of the $\mathcal{SRC}$ language [3, 4], which is used in this paper due to its relevance in the context of the ontological KB query answering.

Note that the goal of the present paper is not to change or criticise the definitions from this area; we simply present the existing work. Our goal is to study the link between the existing work in this area and the existing work in argumentation theory. In the following, we give a general setting knowledge representation language which can
then be instantiated according to properties on rules or constraints and yield equivalent languages to those used by [16] and [8].

A knowledge base is a 3-tuple \( K = (F, R, N) \) composed of three finite sets of formulae: a set \( F \) of facts, a set \( R \) of rules and a set \( N \) of constraints. Let us formally define what we accept as \( F, R \) and \( N \).

**Facts Syntax.** Let \( C \) be a set of constants and \( P = P_1 \cup P_2 \ldots \cup P_n \) a set of predicates of the corresponding arity \( i = 1, \ldots, n \). Let \( V \) be a countably infinite set of *variables*. We define the set of *terms* by \( T = V \cup C \). As usual, given \( i \in \{1, \ldots, n\} \), \( p \in P \) and \( t_1, \ldots, t_i \in T \) we call \( p(t_1, \ldots, t_i) \) an *atom*. If \( \gamma \) is an atom or a conjunction of atoms, we denote by var(\( \gamma \)) the set of variables in \( \gamma \) and by term(\( \gamma \)) the set of terms in \( \gamma \). A *fact* is the existential closure of an atom or an existential closure of a conjunction of atoms. (Note that there is no negation or disjunction in the facts.) As an example, consider \( C = \{Tom\}, P = P_1 \cup P_2 \) with \( P_1 = \{cat, mouse\} \), \( P_2 = \{eats\} \) and \( V = \{x_1, x_2, x_3, \ldots\} \). Then, \( cat(Tom), eats(Tom, x_1) \) are examples of atoms and \( \gamma = \overline{cat(Tom)} \land mouse(x_1) \land eats(Tom, x_1) \) is an example of a conjunction of atoms. It holds that \( \text{var}(\gamma) = \{x_1\} \) and \( \text{term}(\gamma) = \{Tom, x_1\} \). As an example of a fact, consider \( \exists x_1 (cat(Tom) \land mouse(x_1) \land eats(Tom, x_1)) \).

An *interpretation* is a pair \( I = (\Delta, \iota) \) where \( \Delta \) is the interpretation domain (possibly infinite) and \( \iota \), the interpretation function, satisfies:

1. For all \( c \in C \), we have \( c' \in \Delta \).
2. For all \( i \in I \) and for all \( p \in P_i \), we have \( p' \subseteq \Delta^i \).
3. If \( e, e' \in C \) and \( e \neq e' \) then \( e' \neq e'' \).

Note that the third constraint specifies that constants have different names map to different elements of \( \Delta \).

Let \( \gamma \) be an atom or a conjunction of atoms or a fact. We say that \( \gamma \) is true under interpretation \( I \) iff there is a function \( \iota \) which maps the terms (variables and constants) of \( \gamma \) into \( \Delta \) such that for all constants \( c \), it holds that \( \iota(c) = c' \) and for all atoms \( p(t_1, \ldots, t_i) \) appearing in \( \gamma \), it holds that \( \langle \iota(t_1), \ldots, \iota(t_i) \rangle \in p' \). For a set \( F \) containing any combination of atoms, conjunctions of atoms and facts, we say that \( F \) is true under interpretation \( I \) iff there is a function \( \iota \) which maps the terms (variables and constants) of all formulae in \( F \) into \( \Delta \) such that for all constants \( c \), it holds that \( \iota(c) = c' \) and for all atoms \( p(t_1, \ldots, t_i) \) appearing in formulae of \( F \), it holds that \( \langle \iota(t_1), \ldots, \iota(t_i) \rangle \in p' \). Note that this means that for example sets \( F_1 = \{ \exists x (cat(x) \land dog(x)) \} \) and \( F_2 = \{ \exists x (cat(x)), \exists x (dog(x)) \} \) are true under exactly the same set of interpretations. Namely, in both cases, variable \( x \) is mapped to an object of \( \Delta \). On the other hand, there are some interpretations under which set \( F_3 = \{ \exists x_1 (cat(x_1)), \exists x_2 (dog(x_2)) \} \) is true whereas \( F_1 \) and \( F_2 \) are not.

If \( \gamma \) is true in \( I \) we say that \( I \) is a model of \( \gamma \). Let \( \gamma' \) be an atom, a conjunction of atoms or a fact. We say that \( \gamma \) is a logical consequence of \( \gamma' \) (\( \gamma' \) entails \( \gamma \), denoted \( \gamma' \models \gamma \)) iff all models of \( \gamma \) are models of \( \gamma' \). If a set \( F \) is true in \( I \) we say that \( I \) is a model of \( F \). We say that a formula \( \gamma \) is a logical consequence of a set \( F \) (denoted \( F \models \gamma \)) iff all models of \( F \) are models of \( \gamma \). We say that a set \( G \) is a logical consequence of a set \( F \) (denoted \( F \models G \)) if and only if all models of \( F \) are models of \( G \). We say that two sets \( F \) and \( G \) are logically equivalent (denoted \( F \equiv G \)) if and only if \( F \models G \) and \( G \models F \).
Given a set of variables $X$ and a set of terms $T$, a substitution $\sigma$ of $X$ by $T$ is a mapping from $X \times T$ (denoted $\sigma : X \rightarrow T$). Given an atom or a conjunction of atoms $\gamma$, $\sigma(\gamma)$ denotes the expression obtained from $\gamma$ by replacing each occurrence of $x \in X \cap \text{var}(\gamma)$ by $\sigma(x)$. If a fact $F$ is the existential closure of a conjunction $\gamma$ then we define $\sigma(F)$ as the existential closure of $\sigma(\gamma)$. Finally, let us define homomorphism.

Let $F$ and $F'$ be atoms, conjunctions of atoms or facts (it is not necessarily the case that $F$ and $F'$ are of the same type, e.g. $F$ can be an atom and $F'$ a conjunction of atoms). Let $\sigma$ be a substitution such that $\sigma : \text{var}(F) \rightarrow \text{term}(F')$. We say that $\sigma$ is a homomorphism from $F$ to $F'$ if and only if the set of atoms appearing in $\sigma(F)$ is a subset of the set of atoms appearing in $\sigma(F')$. For example, let $F = \text{cat}(x_1)$ and $F' = \text{cat}(\text{Tom}) \land \text{mouse}(\text{Jerry})$. Let $\sigma : \text{var}(F) \rightarrow \text{term}(F')$ be a substitution such that $\sigma(x_1) = \text{Tom}$. Then, $\sigma$ is a homomorphism from $F$ to $F'$ since the atoms in $\sigma(F)$ are $\{\text{cat}(\text{Tom})\}$ and the atoms in $\sigma(F')$ are $\{\text{cat}(\text{Tom}), \text{mouse}(\text{Jerry})\}$.

Note that it well is known that $F' \models F$ if and only if there is a homomorphism from $F$ to $F'$ [12].

**Rules.** A rule $R$ is a formula $\forall x_1, \ldots, \forall x_n \forall y_1, \ldots, \forall y_m \ (H(x_1, \ldots, x_n, y_1, \ldots, y_m) \rightarrow \exists z_1, \ldots, \exists z_k \ C(y_1, \ldots, y_m, z_1, \ldots, z_k))$ where $H$, the hypothesis, and $C$, the conclusion, are atoms or conjunctions of atoms, $n, m, k \in \{0, 1, \ldots\}$, $x_1, \ldots, x_n$ are the variables appearing in $H$, $y_1, \ldots, y_m$ are the variables appearing in both $H$ and $C$ and $z_1, \ldots, z_k$ are the new variables introduced in the conclusion. As two examples of rules, consider $\forall x_1 (\text{cat}(x_1) \rightarrow \text{mouse}(x_1))$ or $\forall x_1 (\text{mouse}(x_1) \rightarrow \exists z_1 (\text{cat}(z_1) \land \text{cat}(z_1, x_1)))$.

Reasoning consists of applying rules on the set and thus inferring new knowledge. A rule $R = (H, C)$ is applicable to set $F$ if and only if there exists $F' \subseteq F$ such that there is a homomorphism $\sigma$ from the hypothesis of $R$ to the conjunction of elements of $F'$. For example, rule $\forall x_1 (\text{cat}(x_1) \rightarrow \text{mouse}(x_1))$ is applicable to set $\{\text{cat}(\text{Tom})\}$, since there is a homomorphism from $\text{cat}(x_1)$ to $\text{cat}(\text{Tom})$. If rule $R$ is applicable to set $F$, the application of $R$ to $F$ according to $\sigma$ produces a set $F' \cup \{\pi(C)\}$. In our example, the produced set is $\{\text{cat}(\text{Tom}), \text{mouse}(\text{Tom})\}$. We then say that the new set (which includes the old one and adds the new information to it) is an immediate derivation of $F$ by $R$. This new set is often denoted by $R(F)$. Thus, applying a rule on a set produces a new set.

Let $F$ be a subset of $F$ and let $R$ be a set of rules. A set $F_i$ is called an $R$-derivation of $F$ if there is a sequence of sets (called a derivation sequence) $(F_0, F_1, \ldots, F_n)$ such that:

- $F_0 \subseteq F$
- $F_0$ is $R$-consistent
- for every $i \in \{1, \ldots, n-1\}$, it holds that $F_i$ is an immediate derivation of $F_{i-1}$
- (no formula in $F_n$ contains a conjunction and $F_n$ is an immediate derivation of $F_{n-1}$) or $F_n$ is obtained from $F_{n-1}$ by conjunction elimination.

Conjunction elimination is the following procedure: while there exists at least one conjunction in at least one formula, take an arbitrary formula $\varphi$ containing a conjunction. If $\varphi$ is of the form $\varphi = \psi \land \psi'$ then exchange it with two formulae $\psi$ and $\psi'$. If $\varphi$ is of the form $\exists x (\psi \land \psi')$ then exchange it with two formulae $\exists x (\psi)$ and $\exists x (\psi')$. The idea is just to start with an $R$-consistent set and apply (some of the) rules. The only
technical detail is that the conjunctions are eliminated from the final result. So if the last set in a sequence does not contain conjunctions, nothing is done. Else, we eliminate those conjunctions. This technicality is needed in order to stay as close as possible to the procedures used in the literature in the case when the knowledge base is consistent.

Given a set \( \{F_0, \ldots, F_k\} \subseteq F \) and a set of rules \( R \), the closure of \( \{F_0, \ldots, F_k\} \) with respect to \( R \), denoted \( \text{Cl}_R(\{F_0, \ldots, F_k\}) \), is defined as the smallest set (with respect to \( \subseteq \)) which contains \( \{F_0, \ldots, F_k\} \), and is closed for \( R \)-derivation (that is, for every \( R \)-derivation \( F_0 \) of \( \{F_0, \ldots, F_k\} \), we have \( F_0 \subseteq \text{Cl}_R(\{F_0, \ldots, F_k\}) \)). Finally, we say that a set \( F \) and a set of rules \( R \) entail a fact \( G \) (and we write \( F, R \models G \)) iff the closure of the facts by all the rules entails \( F \) (i.e. if \( \text{Cl}_R(F) \models G \)).

As an example, consider a set of facts \( F = \{\text{eat(Tom)}, \text{small(Tom)}\} \) and the rule set \( R = \{R_1 = \forall x_1 (\text{eat}(x_1) \rightarrow \text{miaw}(x_1) \land \text{animal}(x_1)), R_2 = \forall x_1 (\text{miaw}(x_1) \land \text{small}(x_1) \rightarrow \text{cate}(x_1))\} \). Then, \( F_0, F_1, F_2 \) is a derivation sequence, where \( F_0 = \{\text{eat(Tom)}, \text{small(Tom)}\} \), \( F_1 = R_1(F_0) = \{\text{eat(Tom)}, \text{miaw(Tom)}, \text{small(Tom)} \land \text{animal}(x_1)\} \), \( F_2 = \{\text{eat(Tom)}, \text{small(Tom)}, \text{miaw(Tom)} \land \text{animal}(x_1), \text{cate}(x_1)\} \) and \( F_3 = \{\text{eat(Tom)}, \text{small(Tom)}, \text{miaw(Tom)}, \text{animal}(x_1)\} \).

We conclude the presentation on rules in \( 
\text{SRC} \) by a remark on performing union on facts when they are viewed as sets of atoms. In order to preserve semantics the union is done by renaming variables. For example, let us consider a fact \( F_1 = \{\exists x \text{cat}(x)\} \) and a fact \( F_2 = \{\exists x \text{animal}(x)\} \). Then the fact \( F = F_1 \cup F_2 \) is the union of the two fact after variable naming has been performed: \( F = \{\exists x \exists y \text{cat}(x), \exists x \exists y \text{animal}(x, y)\} \).

Constraints. A constraint is a formula \( \forall x_1 \ldots \forall x_n (H(x_1, \ldots, x_n) \rightarrow \bot) \), where \( H \) is an atom or a conjunction of atoms and \( n \in \{0, 1, 2, \ldots\} \). Equivalently, a constraint can be written as \( \neg \exists x_1, \ldots, \exists x_n H(x_1, \ldots, x_n) \). As an example of a constraint, consider \( \forall x_1 (\text{cat}(x_1) \land \text{dog}(x_1) \rightarrow \bot) \). \( H(x_1, \ldots, x_n) \) is called the hypothesis of the constraint.

Given a knowledge base \( K = (F, R, N) \), a set \( \{F_1, \ldots, F_k\} \subseteq F \) is said to be \( R \)-incumbent if and only if there exists a constraint \( N \in N \) such that \( \{F_1, \ldots, F_k\} \models H_N \), where \( H_N \) denotes the existential closure of the hypothesis of \( N \). A set is consistent if and only if it is not \( R \)-inconsistent. A set \( \{F_1, \ldots, F_k\} \subseteq F \) is called \( R \)-inconsistent if and only if there exists a constraint \( N \in N \) such that \( \text{Cl}_R(\{F_1, \ldots, F_k\}) \models H_N \), where \( H_N \) denotes the existential closure of the hypothesis of \( N \).

A set of facts is said to be \( R \)-consistent if and only if it is not \( R \)-inconsistent. A knowledge base \( (F, R, N) \) is said to be \( R \)-consistent if and only if \( F \) is \( R \)-consistent. A knowledge base is \( R \)-inconsistent if and only if it is not \( R \)-consistent.

Example 1. Let us consider the following knowledge base \( K = (F, R, N) \), with: \( F = \{\text{eat(Tom)}, \text{bark(Tom)}\} \), \( R = \{\forall x_1 (\text{eat}(x_1) \rightarrow \text{miaw}(x_1))\} \), \( N = \{\forall x_1 (\text{bark}(x_1) \land \text{miaw}(x_1) \rightarrow \bot)\} \). The only rule in the knowledge base is applicable to the set \( \{\text{eat(Tom)}, \text{bark(Tom)}\} \) and its immediate derivation produces the set \( \{\text{eat(Tom)}, \text{bark(Tom)}, \text{miaw(Tom)}\} \). We see that \( \text{Cl}_R(F) \models \exists x_1 (\text{bark}(x_1) \land \text{miaw}(x_1)) \), thus the KB is inconsistent.

Given a knowledge base, one can ask a conjunctive query in order to know whether something holds or not. Without loss of generality we consider in this paper boolean conjunctive queries (which are facts). As an example of a query, take \( \exists x \text{cat}(x) \). The answer to query \( \alpha \) is positive if and only if \( F, R \models \alpha \).
2.1 Query Answering over Inconsistent Ontological Knowledge Bases

Notice that (like in classical logic), if a knowledge base $K = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ is inconsistent, then everything is entailed from it. In other words, every query is true. Thus, the approach we described until now is not robust enough to deal with inconsistent information. However, there are cases when the knowledge base is inconsistent; this phenomenon has attracted particular attention during the recent years [8, 16]. For example, the set $\mathcal{F}$ may be obtained by combining several sets of facts, coming from different agents. In this paper, we study a general case when $K$ is inconsistent without making any hypotheses about the origin of this inconsistency. Thus, our results can be applied to an inconsistent base independently of how it is obtained.

A common solution [8, 16] is to construct maximal (with respect to set inclusion) consistent subsets of $K$. Such subsets are called repairs. Formally, given a knowledge base $K = (\mathcal{F}, \mathcal{R}, \mathcal{N})$, define:

$$\mathcal{R}_\text{repair}(K) = \{\mathcal{F}' \subseteq \mathcal{F} \mid \mathcal{F}' \text{ is maximal for } \subseteq \text{ R-consistent set}\}$$

We now mention a very important technical detail. In some papers, a set of formulae is identified with the conjunction of those formulae. This is not of particular significance when the knowledge base is consistent. However, in case of an inconsistent knowledge base, this makes a big difference. Consider for example $K_1 = (\mathcal{F}_1, \mathcal{R}_1, \mathcal{N}_1)$ with $\mathcal{F}_1 = \{\text{dog(Tom)}, \text{cat(Tom)}\}$, $\mathcal{R}_1 = \emptyset$ and $\mathcal{N}_1 = \{\forall x (\text{dog}(x) \land \text{cat}(x) \rightarrow \bot)\}$, compared with $K_2 = (\mathcal{F}_2, \mathcal{R}_2, \mathcal{N}_2)$ with $\mathcal{F}_2 = \{\text{dog(Tom)} \land \text{cat(Tom)}\}$, $\mathcal{R}_2 = \emptyset$ and $\mathcal{N}_2 = \{\forall x (\text{dog}(x) \land \text{cat}(x) \rightarrow \bot)\}$. In this case, according to the definition of a repair, $K_1$ would have two repairs and $K_2$ would have no repairs at all. We could proceed like this, but we find it confusing given the existing literature in this area. This is why, in order to be completely precise, from now on we suppose that $\mathcal{F}$ does not contain conjunctions. Namely, $\mathcal{F}$ is supposed to be a set composed of atoms and of existential closures of atoms. One could believe that this reduces the expressibility of the language, consider for example $\mathcal{F}_1 = \{\exists x (\text{dog}(x)), \exists x (\text{black}(x))\}$ as opposed to $\mathcal{F}_2 = \{\exists x (\text{dog}(x) \land \text{black}(x))\}$. Namely, in classical first order logic, $\mathcal{F}_1$ and $\mathcal{F}_2$ do not have the same models. However, in $\mathcal{SRC}$, $\mathcal{F}_1$ and $\mathcal{F}_2$ have the same models (see the definition of an interpretation).

Once the repairs calculated, there are different ways to calculate the set of facts that follow from an inconsistent knowledge base. For example, we may want to accept a query if it is entailed in all repairs (AR semantics).

**Definition 1.** Let $K = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ be a knowledge base and let $\alpha$ be a query. Then $\alpha$ is **AR-entailed** from $K$, written $K \models_{AR} \alpha$ if for every repair $\mathcal{A}' \in \mathcal{R}_\text{repair}(K)$, it holds that $\mathcal{G}_R(\mathcal{A}') \models \alpha$.

Another possibility is to check whether the query is entailed from the intersection of closed repairs (ICR semantics).

**Definition 2.** Let $K = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ be a knowledge base and let $\alpha$ be a query. Then $\alpha$ is **ICR-entailed** from $K$, written $K \models_{ICR} \alpha$ if $\bigcap_{\mathcal{A}' \in \mathcal{R}_\text{repair}(K)} \mathcal{G}_R(\mathcal{A}') \models \alpha$.
Example 2 (Example 1 Cont.). \( \text{Repair}(K) = \{ R_1, R_2 \} \) with \( R_1 = \{ \text{cat}(Tom) \} \) and \( R_2 = \{ \text{bark}(Tom) \} \). \( C_{\xi}(R_1) = \{ \text{cat}(Tom), \text{nois}(Tom) \} \), \( C_{\xi}(R_2) = \{ \text{bark}(Tom) \} \). It is not the case that \( K \models_{\text{ICR}} \text{cat}(Tom) \).

Finally, another possibility is to consider the intersection of all repairs and then close this intersection under the rules (IAR semantics).

**Definition 3.** Let \( K = (F, R, N) \) be a knowledge base and let \( \alpha \) be a query. Then \( \alpha \) is **IAR-entailed** from \( K \), written \( \models_{\text{IAR}} \alpha \) iff \( C_{\xi}(\bigcap_{\alpha \in \text{Repair}(K)}) \models \alpha \).

The three semantics can yield different results [16, 8], as illustrated by the next two examples.

Example 3. (ICR and IAR different from AR) Consider \( K = (F, R, N) \), with: \( F = \{ \text{hasCat}(Tom), \text{hasMouse}(Jerry) \} \), intuitively, we have a cat (called Tom) and a mouse (called Jerry); \( R = \{ \forall x (\text{hasCat}(x) \rightarrow \text{hasAnimal}(x)) \}, N = \{ \forall x \forall y (\text{cat}(x) \land \text{mouse}(y) \rightarrow \bot) \} \), meaning that we cannot have both a cat and a mouse (since the cat would eat the mouse). There are two repairs: \( R_1 = \{ \text{hasCat}(Tom) \} \) and \( R_2 = \{ \text{hasMouse}(Jerry) \}, C_{\xi}(R_1) = \{ \text{hasCat}(Tom), \text{hasAnimal}(Tom) \} \) and \( C_{\xi}(R_2) = \{ \text{hasMouse}(Jerry), \text{hasAnimal}(Jerry) \} \). Consider a query \( \alpha = \exists x \text{hasAnimal}(x) \) asking whether we have an animal. It holds that \( K \models_{\text{AR}} \alpha \) since \( C_{\xi}(R_1) \models \alpha \) and \( C_{\xi}(R_2) \models \alpha \), but neither \( K \models_{\text{ICR}} \alpha \) (since \( C_{\xi}(R_1) \cap C_{\xi}(R_2) = \emptyset \)) nor \( K \models_{\text{IAR}} \alpha \) (since \( R_1 \cap R_2 = \emptyset \)).

Example 4. (AR and ICR different from IAR) Consider \( K = (F, R, N) \), with: \( F = \{ \text{cat}(Tom), \text{dog}(Tom) \}, R = \{ \forall x (\text{cat}(x) \rightarrow \text{animal}(x)) \}, N = \{ \forall x (\text{cat}(x) \land \text{dog}(x) \rightarrow \bot) \} \).

We have \( \text{Repair}(K) = \{ R_1, R_2 \} \) with \( R_1 = \{ \text{cat}(Tom) \} \) and \( R_2 = \{ \text{dog}(Tom) \}, C_{\xi}(R_1) = \{ \text{cat}(Tom), \text{animal}(Tom) \} \), \( C_{\xi}(R_2) = \{ \text{dog}(Tom), \text{animal}(Tom) \} \).

It is not the case that \( K \models_{\text{IAR}} \exists x (\text{animal}(x)) \) (since \( R_1 \cap R_2 = \emptyset \)). However, \( K \models_{\text{ICR}} \exists x (\text{animal}(x)) \). This is due to the fact that \( C_{\xi}(R_1) \models \exists x (\text{animal}(x)) \) and \( C_{\xi}(R_2) \models \exists x (\text{animal}(x)) \). Also, we have \( K \models_{\text{ICR}} \exists x (\text{animal}(x)) \) since \( C_{\xi}(R_1) \cap C_{\xi}(R_2) = \{ \text{animal}(Tom) \} \).

3 Argumentation over Inconsistent Ontological Knowledge Bases

This section shows that it is possible to define an instantiation of Dung’s abstract argumentation theory [15] that can be used to reason with an inconsistent ontological KB.

We first define the notion of an argument. For a set of formulae \( G = \{ G_1, \ldots, G_n \} \), notation \( \bigwedge G \) is used as an abbreviation for \( G_1 \land \cdots \land G_n \).

**Definition 4.** Given a knowledge base \( K = (F, R, N) \), an argument \( a \) is a tuple \( a = (F_0, F_1, \ldots, F_n) \) where:

\( (F_0, \ldots, F_{n-1}) \) is a derivation sequence with respect to \( K \).
Example 5 (Example 2 Cont.). Consider $a = \{\{\text{eat(Tom)}\}\}, \{\text{cat(Tom)}\}$, $\{\text{miaaw(Tom)}\}$ and $b = \{\{\text{bark(Tom)}\}, \text{bark(Tom)}\}$ as two examples of arguments.

This is a straightforward way to define an argument when dealing with $\mathcal{SR}$Language, since this way, an argument corresponds to a derivation.

To simplify the notation, from now on, we suppose that we are given a fixed knowledge base $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ and do not explicitly mention $\mathcal{F}$, $\mathcal{R}$ nor $\mathcal{N}$ if not necessary. Let $a = \{F_1, \ldots, F_n\}$ be an argument. Then, we denote $\text{Supp}(a) = F_n$ and $\text{Conc}(a) = F_1$. Let $S \subseteq \mathcal{F}$ a set of facts, $\text{Arg}(S)$ is defined as the set of all arguments $a$ such that $\text{Supp}(a) \subseteq S$. Note that the set $\text{Arg}(S)$ is also dependent on the set of rules and the set of constraints, but for simplicity reasons, we do not write $\text{Arg}(S, \mathcal{R}, \mathcal{N})$ when it is clear to which $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ we refer to. Finally, let $E$ be a set of arguments. The base of $E$ is defined as the union of the argument supports: $\text{Base}(E) = \bigcup_{a \in E} \text{Supp}(a)$.

Arguments may attack each other, which is captured by a binary attack relation $\text{att} \subseteq \text{Arg}(\mathcal{F}) \times \text{Arg}(\mathcal{F})$. Recall that the repairs are the subsets of $\mathcal{F}$ while the set $\mathcal{R}$ is always taken as a whole. This means that the authors of the semantics used to deal with an inconsistent ontological KB envisage the set of facts as inconsistent and the set of rules as consistent. When it comes to the attack relation, this means that we only need the so-called “assumption attack” since, roughly speaking, all the inconsistency “comes from the facts”.

Definition 5. Let $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ be a knowledge base and let $a$ and $b$ be two arguments. The argument $a$ attacks argument $b$, denoted $(a, b) \in \text{att}$, if and only if there exists $\varphi \in \text{Supp}(b)$ such that the set $(\text{Conc}(a), \varphi)$ is $\mathcal{R}$-inconsistent.

This attack relation is not symmetric. To see why, consider the following example. Let $\mathcal{F} = \{p(m), q(m), r(m)\}, \mathcal{R} = \emptyset, \mathcal{N} = \{\forall x (p(x) \land q(x) \land r(x)) \rightarrow \bot\}$. Let $a = \{\{p(m), q(m)\}, \{p(m) \land q(m)\}\}$, $b = \{\{r(m)\}, \{r(m)\}\}$. We have $(a, b) \in \text{att}$ and $(b, a) \notin \text{att}$. Note that using attack relations which are not symmetric is very common in argumentation literature. Moreover, symmetric attack relation have been criticised for violating some desirable properties [1].

Definition 6. Given a knowledge base $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$, the corresponding argumentation framework $\mathcal{AF}_\mathcal{K}$ is a pair $(\mathcal{A} = \text{Arg}(\mathcal{F}), \text{att})$ where $\mathcal{A}$ is the set of arguments that can be constructed from $\mathcal{F}$ and $\text{att}$ is the corresponding attack relation as specified in Definition 5.

Let $E \subseteq \mathcal{A}$ and $a \in \mathcal{A}$. We say that $E$ is conflict free if there exists no arguments $a, b \in \mathcal{E}$ such that $(a, b) \in \text{att}$. $E$ defends $a$ if for every argument $b \in \mathcal{A}$, if we have $(b, a) \in \text{att}$ then there exists $c \in E$ such that $(c, b) \in \text{att}$.

$E$ is admissible if it is conflict free and defends all its arguments. $E$ is a complete extension if $E$ is an admissible set which contains all the arguments it defends. $E$ is a preferred extension if it is maximal (with respect to set inclusion) admissible set. $E$ is a stable extension if it is conflict free and for all $a \in \mathcal{A} \setminus E$, there exists an argument $b \in E$ such that $(b, a) \in \text{att}$.
$E$ is a grounded extension iff $E$ is a minimal (for set inclusion) complete extension.
If a semantics returns exactly one extension for every argumentation framework, then it is called a single-extension semantics.
For an argumentation framework $AS = (A, At)$ we denote by $Ext_x(AS)$ (or by $Ext_x(A, At)$) the set of its extensions with respect to semantics $x$. We use the abbreviations $c$, $p$, $s$, and $g$ for respectively complete, preferred, stable and grounded semantics.
An argument is sceptically accepted if it is in all extensions, credulously accepted if it is in at least one extension and rejected if it is not in any extension.

Finally, we introduce two definitions allowing us to reason over such an argumentation framework. The output of an argumentation framework is usually defined [10, Definition 12] as the set of conclusions that appear in all the extensions (under a given semantics).

**Definition 7 (Output of an argumentation framework).** Let $K = (F, R, N)$ be a knowledge base and $AF_K$ the corresponding argumentation framework. The output of $AF_K$ under semantics $x$ is defined as:

$$\text{Output}_x(AF_K) = \bigcap_{E \in Ext_x(AF_K)} \text{Concl}(E).$$

In the degenerate case when $Ext_x(AF_K) = \emptyset$, we define $\text{Output}(AF_K) = \emptyset$ by convention.

Note that the previous definition asks for existence of a conclusion in every extension. This kind of acceptance is usually referred to as sceptical acceptance. We say that a query $\alpha$ is sceptically accepted if it is a logical consequence of the output of $AF_K$:

**Definition 8 (Sceptical acceptance of a query).** Let $K = (F, R, N)$ be a knowledge base and $AF_K$ the corresponding argumentation framework. A query $\alpha$ is sceptically accepted under semantics $x$ if and only if $\text{Output}_x(AF_K) \models \alpha$.

It is possible to make an alternative definition, which uses the notion of universal acceptance instead of sceptical one. According to universal criteria, a query $\alpha$ is accepted if it is a logical consequence of conclusions of every extension:

**Definition 9 (Universal acceptance of a query).** Let $K = (F, R, N)$ be a knowledge base and $AF_K$ the corresponding argumentation framework. A query $\alpha$ is universally accepted under semantics $x$ if and only if for every extension $E_x \in Ext_x(AF_K)$, it holds that $\text{Concl}(E_x) \models \alpha$.

In general, universal and sceptical acceptance of a query do not coincide. Take for instance the KB from Example 3, construct the corresponding argumentation framework, and compare the sets of universally and sceptically accepted queries under preferred semantics.

Note that for single-extension semantics (e.g. grounded), the notions of sceptical and universal acceptance coincide. So we simply use word “accepted” in this context.

**Definition 10 (Acceptance of a query).** Let $K = (F, R, N)$ be a knowledge base, $AF_K$ the corresponding argumentation framework, $x$ a single-extension semantics and let $E$ be the unique extension of $AF_K$. A query $\alpha$ is accepted under semantics $x$ if and only if $\text{Concl}(E) \models \alpha$. 
4 Equivalence between Repairs and Extensions

In this section, we prove two links between the repairs of an ontological KB and the corresponding argumentation framework: Theorem 1 shows that the repairs of the KB correspond exactly to the stable (and preferred, since in this instantiation the stable and the preferred semantics coincide) extensions of the argumentation framework; Theorem 2 proves that the intersection of all the repairs of the KB corresponds to the grounded extension of the argumentation framework.

**Theorem 1.** Let \( K = (F, R, A) \) be a knowledge base, \( AF_K \) the corresponding argumentation framework and \( x \in \{ s, p \} \). Then:

\[
\text{Ext}_x(AF_K) = \{ \text{Arg}(A') \mid A' \in \text{Repair}(K) \}
\]

**Proof.** The plan of the proof is as follows:

1. We prove that \( \{ \text{Arg}(A') \mid A' \in \text{Repair}(K) \} \subseteq \text{Ext}_x(AF_K) \).
2. We prove that \( \text{Ext}_x(AF_K) \subseteq \{ \text{Arg}(A') \mid A' \in \text{Repair}(K) \} \).
3. Since every stable extension is a preferred one [15], we can proceed as follows. From the first item, we have that \( \{ \text{Arg}(A') \mid A' \in \text{Repair}(K) \} \subseteq \text{Ext}_x(AF_K) \), thus the theorem holds for preferred semantics. From the second item we have that \( \text{Ext}_x(AF_K) \subseteq \{ \text{Arg}(A') \mid A' \in \text{Repair}(K) \} \), thus the theorem holds for stable semantics.

1. We first show \( \{ \text{Arg}(A') \mid A' \in \text{Repair}(K) \} \subseteq \text{Ext}_x(AF_K) \). Let \( A' \in \text{Repair}(K) \) and let \( \mathcal{E} = \text{Arg}(A') \). Let us prove that \( \mathcal{E} \) is a stable extension of \( (\text{Arg}(F), \text{Att}) \).

   We first prove that \( \mathcal{E} \) is conflict-free. By means of contradiction suppose the contrary, i.e. let \( (a, b) \in \mathcal{E} \) such that \( (a, b) \in \text{Att} \). From the definition of attack, there exists \( \varphi \in \text{Supp}(b) \) such that \( \{ \text{Conc}(a), \varphi \} \) is \( R \)-inconsistent. Thus \( \text{Supp}(a) \cup \{ \varphi \} \) is \( R \)-inconsistent; consequently \( A' \) is \( R \)-inconsistent, contradiction. Therefore \( \mathcal{E} \) is conflict-free.

   Let us now prove that \( \mathcal{E} \) attacks all arguments outside the set. Let \( b \in \text{Arg}(F) \setminus \text{Arg}(A') \) and let \( \varphi \in \text{Supp}(b) \), such that \( \varphi \notin A' \). Let \( A' \) be the set obtained from \( A' \) by conjunction elimination and let \( a = (A', A', A') \). We have \( \varphi \notin A' \), so, due to the set inclusion maximality for the repairs, \( \{ A', A', A' \} \) is \( R \)-inconsistent. Therefore, \( (a, b) \in \text{Att} \). Consequently, \( \mathcal{E} \) is a stable extension.

2. We now need to prove that \( \text{Ext}_x(AF_K) \subseteq \{ \text{Arg}(A') \mid A' \in \text{Repair}(K) \} \). Let \( \mathcal{E} \in \text{Ext}_x(AF_K) \) and let us prove that there exists a repair \( A' \) such that \( \mathcal{E} = \text{Arg}(A') \).

   Let \( S = \text{Base}(\mathcal{E}) \). Let us prove that \( S \) is \( R \)-consistent. Aiming to a contradiction, suppose that \( S \) is \( R \)-inconsistent. Let \( S' \subseteq S \) be such that (1) \( S' \) is \( R \)-inconsistent and (2) every proper set of \( S' \) is \( R \)-consistent. Let us denote \( S' = \{ \varphi_1, \varphi_2, ..., \varphi_n \} \). Let \( (a, b) \in \text{Att} \) be an argument such that \( \varphi_n \in \text{Supp}(a) \). Let \( S' \) be the set obtained from \( S' \setminus \{ \varphi \} \) by conjunction elimination and let \( a' = (S' \setminus \{ \varphi_n \}, S', S') \). We have that \( (a', a) \in \text{Att} \). Since \( \mathcal{E} \) is conflict-free, then \( a' \notin \mathcal{E} \). Since \( \mathcal{E} \) is an admissible set there exists \( b \in \mathcal{E} \) such that \( (b, a') \in \text{Att} \). Since \( b \) attacks \( a' \) then there exists

---

1 Recall that \( s \) stands for stable and \( p \) for preferred semantics.
$i \in \{1, 2, \ldots, n - 1\}$ such that $\{\text{Con}(h), \varphi_i\}$ is $\mathcal{R}$-inconsistent. Since $\varphi_i \in \text{Base}(\mathcal{E})$, then there exists $c \in \mathcal{E}$ such that $\varphi_i \in \text{Supp}(c)$. Thus $(h, c) \in \text{Att}$, contradiction. So it must be that $\mathcal{S}$ is $\mathcal{R}$-consistent.

Let us now prove that there exists no $S' \subseteq \mathcal{F}$ such that $S \subseteq S'$ and $S'$ is $\mathcal{R}$-consistent. We use the proof by contradiction. Thus, suppose that $\mathcal{S}$ is not a maximal $\mathcal{R}$-consistent subset of $\mathcal{F}$. Then, there exists $S' \in \text{Repair}(\mathcal{K})$, such that $S \subseteq S'$. We have that $\mathcal{E} \subseteq \text{Arg}(S)$, since $S = \text{Base}(\mathcal{E})$. Denote $\mathcal{E}' = \text{Arg}(S')$. Since $S \subseteq S'$ then $\text{Arg}(S) \subseteq \mathcal{E}'$. Thus, $\mathcal{E} \subseteq \mathcal{E}'$. From the first part of the proof, $\mathcal{E}' \in \text{Ext}_{\mathcal{K}}(\mathcal{A}\mathcal{F}_{\mathcal{K}})$. Consequently, $\mathcal{E} \in \text{Ext}_{\mathcal{K}}(\mathcal{A}\mathcal{F}_{\mathcal{K}})$. We also know that $\mathcal{E} \in \text{Ext}_{\mathcal{K}}(\mathcal{A}\mathcal{F}_{\mathcal{K}})$. Contradiction, since no preferred set can be a proper subset of another preferred set. Thus, we conclude that $\text{Base}(\mathcal{E}) \in \text{Repair}(\mathcal{K})$.

Let us show that $\mathcal{E} = \text{Arg}(\text{Base}(\mathcal{E}))$. It must be that $\mathcal{E} \subseteq \text{Arg}(S)$. Also, we know (from the first part) that $\text{Arg}(S)$ is a stable and preferred extension, thus the case $\mathcal{E} \not\subseteq \text{Arg}(S)$ is not possible.

3. Now we know that $\{\text{Arg}(A') \mid A' \in \text{Repair}(\mathcal{K})\} \subseteq \text{Ext}_{\mathcal{K}}(\mathcal{A}\mathcal{F}_{\mathcal{K}})$ and $\text{Ext}_{\mathcal{K}}(\mathcal{A}\mathcal{F}_{\mathcal{K}}) \subseteq \{\text{Arg}(A') \mid A' \in \text{Repair}(\mathcal{K})\}$. Theorem follows from those two facts, as explained at the beginning of the proof.

To prove Theorem 2, we first prove the following lemma which says that if there are no rejected arguments under preferred semantics, then the grounded extension is equal to the intersection of all preferred extensions. Note that this result holds for every argumentation framework (not only for the one studied in this paper, where arguments are constructed from an ontological knowledge base). Thus, we only suppose that we are given a set and a binary relation on it (called attack relation).

**Lemma 1.** Let $\mathcal{A} = (\mathcal{A}, \text{Att})$ be an argumentation framework and $\text{GE}$ its grounded extension.

$$\text{GE} = \bigcap_{\mathcal{E} \in \text{Ext}_{\mathcal{K}}(\mathcal{A}\mathcal{F}_{\mathcal{K}})} \mathcal{E}.$$ 

**Proof.** Let $\text{Iope} = \bigcap_{\mathcal{E} \in \text{Ext}_{\mathcal{K}}(\mathcal{A}\mathcal{F}_{\mathcal{K}})} \mathcal{E}$ denote the intersection of all preferred extensions. It is known [15] the $\text{GE} \subseteq \text{Iope}$. Let us prove that in the case when there are no rejected arguments, it also holds the $\text{Iope} \subseteq \text{GE}$. Let $a \in \text{Iope}$. Let us show that no argument $b$ attacks $a$. This holds since every argument $b$ is in at least one preferred extension, say $\mathcal{E}_b$, and $a$ is also in $\mathcal{E}_b$ (since $a$ is in all preferred extensions) thus $b$ does not attack $a$ since both $a$ and $b$ are in $\mathcal{E}_b$, and $\mathcal{E}_b$ is a conflict-free set (since it is a preferred extension). All this means that arguments in $\text{Iope}$ are not attacked. Consequently, they must all belong to the grounded extension. In other words, $\text{Iope} \subseteq \text{GE}$.

We can now, using the previous result, prove the link between the intersection of repairs and the grounded extension.

**Theorem 2.** Let $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ be a knowledge base and $\mathcal{A}\mathcal{F}_{\mathcal{K}}$ the corresponding argumentation framework. Denote the grounded extension of $\mathcal{A}\mathcal{F}_{\mathcal{K}}$ by $\text{GE}$. Then:

$$\text{GE} = \text{Arg}(\bigcap_{A' \in \text{Repair}(\mathcal{K})} A').$$

130
Proof. Denote the intersection of all repairs by $I_{oar} = \bigcap_{A' \in \text{Repair}(K)} A'$ and the intersection of all preferred extensions by $I_{pe} = \bigcap_{A' \in \text{Ext}_p(\mathcal{AF}_K)} A'$. From Theorem 1, we know that $\text{Ext}_p(\mathcal{AF}_K) = \{ \text{Arg}(A') \mid A' \in \text{Repair}(K) \}$. Consequently,

$$I_{pe} = \bigcap_{A' \in \text{Repair}(K)} \text{Arg}(A')$$ (1)

Since every argument has an $R$-consistent support, then its support is in at least one repair. From Theorem 1, that argument is in at least one preferred extension, i.e. it is not rejected. From Lemma 1,

$$I_{pe} = GE$$ (2)

From (1) and (2), we obtain that

$$GE = \bigcap_{A' \in \text{Repair}(K)} \text{Arg}(A')$$ (3)

Note that for every collection $S_1, \ldots, S_n$ of sets of formulae, we have $\text{Arg}(S_1) \cap \ldots \cap \text{Arg}(S_n) = \text{Arg}(S_1 \cap \ldots \cap S_n)$. By applying this rule on the set of all repairs, we obtain:

$$\bigcap_{A' \in \text{Repair}(K)} \text{Arg}(A') = \text{Arg}(I_{oar})$$ (4)

From (3) and (4), we obtain $GE = \text{Arg}(I_{oar})$ which ends the proof.

5 Semantics Equivalence

This section presents the main result of the paper. It proves the links between semantics from argumentation theory (stable, preferred, grounded) and semantics from inconsistent ontology KB query answering (ICR, AR, IAR). More precisely, we show that: (1) sceptical acceptance under stable and preferred semantics corresponds to ICR semantics; (2) universal acceptance under stable and preferred semantics corresponds to AR semantics; (3) acceptance under grounded semantics corresponds to IAR semantics. The proof of Theorem 3 is based on Theorem 1 and the proof of Theorem 4 is derived from Theorem 2.

Theorem 3. Let $K = (\mathcal{F}, R, \mathcal{N})$ be a knowledge base, let $\mathcal{AF}_K$ be the corresponding argumentation framework and let $x$ be a query. Let $x \in \{ s, p \}$ be stable or preferred semantics. Then:

$- K \models_{ICR} \alpha$ if and only if $\alpha$ is sceptically accepted under semantics $x$.

$- K \models_{AR} \alpha$ if and only if $\alpha$ is universally accepted under semantics $x$.

Proof. Theorem 1 implies $\text{Ext}_p(\text{Arg}(\mathcal{F}), \text{Att}) = \{ \text{Arg}(A') \mid A' \in \text{Repair}(K) \}$. In fact, the restriction of function $\text{Arg}$ on $\text{Repair}(K)$ is a bijection between $\text{Repair}(K)$ and $\text{Ext}_p(\mathcal{AF}_K)$. Note also that for every query $\alpha$, for every repair $A'$, we have that $\text{Arg}(A') \models \alpha$ if and only if $\text{Concl}(\text{Arg}(A')) \models \alpha$. By using those two facts, the result of the theorem can be obtained as follows:
- For every query \( \alpha \), we have: \( \mathcal{K} \models_{IAR} \alpha \) if and only if \( \bigcap_{A' \in \text{Repair}(\mathcal{K})} \text{Cl}_{R}(A') \models \alpha \) if and only if \( \bigcap_{E_i \in \text{Ext}_r(\mathcal{AF}_R)} \text{Concs}(E_i) \models \alpha \) if and only if \( \text{Output}_r(\mathcal{AF}_R) \models \alpha \) if and only if \( \alpha \) is skeptically accepted.

- For every query \( \alpha \), we have: \( \mathcal{K} \models_{AR} \alpha \) if and only if for every \( A' \in \text{Repair}(\mathcal{K}), \text{Cl}_{R}(A') \models \alpha \) if and only if for every \( E_i \in \text{Ext}_r(\mathcal{AF}_R), \text{Concs}(E_i) \models \alpha \) if and only if \( \alpha \) is universally accepted.

**Theorem 4.** Let \( \mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N}) \) be a knowledge base, let \( \mathcal{AF}_R \) be the corresponding argumentation framework and let \( \alpha \) be a query. Then:

\[ \mathcal{K} \models_{IAR} \alpha \iff \alpha \text{ is accepted under grounded semantics.} \]

**Proof.** Let us denote the grounded extension of \( \mathcal{AF}_R \) by \( \text{GE} \) and the intersection of all repairs by \( \text{Ioar} = \bigcap_{A' \in \text{Repair}(\mathcal{K})} A' \). From Definition 10, we have:

\[ \alpha \text{ is accepted under grounded semantics iff } \text{Concs}(\text{GE}) \models \alpha. \] (5)

From Theorem 2, we have:

\[ \text{GE} = \text{Arg}(\text{Ioar}). \] (6)

Note also that for every set of facts \( \{F_1, \ldots, F_n\} \) and for every query \( \alpha \), we have that \( \text{Cl}_{R}(\{F_1, \ldots, F_n\}) \models \alpha \) if and only if \( \text{Concs}(\text{arg}(\{F_1, \ldots, F_n\})) \models \alpha \). Thus,

\[ \text{Cl}_{R}(\text{Ioar}) \models \alpha \text{ if and only if } \text{Concs}(\text{arg}(\text{Ioar})) \models \alpha. \] (7)

From (6) and (7) we have that:

\[ \text{Cl}_{R}(\text{Ioar}) \models \alpha \text{ if and only if } \text{Concs}(\text{GE}) \models \alpha. \] (8)

From Definition 3, one obtains:

\[ \text{Cl}_{R}(\text{Ioar}) \models \alpha \text{ if and only if } \mathcal{K} \models_{IAR} \alpha. \] (9)

The theorem now follows from (5), (8) and (9).

### 6 Postulates

In this section, we prove that the framework we propose in this paper satisfies the rationality postulates for instantiated argumentation frameworks [10]. We first prove the indirect consistency postulate.

**Proposition 1 (Indirect consistency).** Let \( \mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N}) \) be a knowledge base, \( \mathcal{AF}_R \) the corresponding argumentation framework and \( x \in \{s, p, gy\} \). Then:

- for every \( E_i \in \text{Ext}_r(\mathcal{AF}_R) \), \( \text{Cl}_{R}(\text{Concs}(E_i)) \) is a consistent set
- \( \text{Cl}_{R}(\text{Output}_r(\mathcal{AF}_R)) \) is a consistent set.

**Proof.**
Let $\mathcal{E}$ be a stable or a preferred extension of $\mathcal{AF}_K$. From Theorem 1, there exists a repair $A' \in \text{Repair}(K)$ such that $\mathcal{E} = \text{Arg}(A')$. Note that $\text{Conc}(\mathcal{E}) = \text{CL}_R(A') \cup \{\alpha \mid \text{CL}_R(A) \models \alpha\}$ (this follows directly from Definition 4). Consequently, the set of $R$-derivations of $\text{Conc}(\mathcal{E})$ and the set of $R$-derivations of $\text{CL}_R(A')$ coincide. Formally, $\text{CL}_R(\text{CL}_R(A')) = \text{CL}_R(\text{Conc}(\mathcal{E}))$. Since $\text{CL}_R$ is idempotent, this means that $\text{CL}_R(A') = \text{CL}_R(\text{Conc}(\mathcal{E}))$. Since $\text{CL}_R(A')$ is consistent, then $\text{CL}_R(\text{Conc}(\mathcal{E}))$ is consistent.

Let us now consider the case of grounded semantics. Denote $\text{GE}$ the grounded extension of $\mathcal{AF}_K$. We have just seen that for every $\mathcal{E} \in \text{Ext}_p(\mathcal{AF}_K)$, it holds that $\text{CL}_R(\text{Conc}(\mathcal{E}))$ is a consistent set. Since the grounded extension is a subset of the intersection of all the preferred extensions [15], and since there is at least one preferred extension, say $\mathcal{E}_i$, then $\mathcal{GE} \subseteq \mathcal{E}_i$. Since $\text{CL}_R(\text{Conc}(\mathcal{E}_i))$ is consistent then $\text{CL}_R(\text{Conc}(\text{GE}))$ is also consistent.

Consider the case of stable or preferred semantics. Let us prove $\text{CL}_R(\text{Output}_p(\mathcal{AF}_K))$ is a consistent set. Recall that $\text{Output}_p(\mathcal{AF}_K) = \bigcap_{\mathcal{E} \in \text{Conc}(\mathcal{AF}_K)} \text{Conc}(\mathcal{E})$. Since every knowledge base has at least one repair then, according to Theorem 1, there is at least one stable or preferred extension $\mathcal{E}_i$. From Definition 7, we have that $\text{Output}_p(\mathcal{AF}_K) \subseteq \text{Conc}(\mathcal{E}_i)$. $\text{Conc}(\mathcal{E}_i)$ is $R$-consistent thus $\text{Output}_p(\mathcal{AF}_K)$ is $R$-consistent. In other words, $\text{CL}_R(\text{Output}_p(\mathcal{AF}_K))$ is consistent. Note that in the case of grounded semantics the second part of the proposition follows directly from the first one, since $\text{CL}_R(\text{Output}_p(\mathcal{AF}_K)) = \text{CL}_R(\text{Conc}(\text{GE}))$.

Since our instantiation satisfies indirect consistency then it also satisfies direct consistency. This comes from $R$-consistency definition; namely, if a set is $R$-consistent, then it is necessarily consistent. Thus, we obtain the following corollary.

**Corollary 1 (Direct consistency).** Let $K = (\mathcal{F}, R, N')$ be a knowledge base, $\mathcal{AF}_K$ the corresponding argumentation framework and $x \in \{s, p, g\}$, Then:

- for every $\mathcal{E} \in \text{Ext}_p(\mathcal{AF}_K)$, $\text{Conc}(\mathcal{E})$ is a consistent set
- $\text{Output}_p(\mathcal{AF}_K)$ is a consistent set.

We now also prove that the present argumentation formalism also satisfies the closure postulate.

**Proposition 2 (Closure).** Let $K = (\mathcal{F}, R, N')$ be a knowledge base, $\mathcal{AF}_K$ the corresponding argumentation framework and $x \in \{s, p, g\}$. Then:

- for every $\mathcal{E} \in \text{Ext}_p(\mathcal{AF}_K)$, $\text{Conc}(\mathcal{E}) = \text{CL}_R(\text{Conc}(\mathcal{E}))$
- $\text{Output}_p(\mathcal{AF}_K) = \text{CL}_R(\text{Output}_p(\mathcal{AF}_K))$.

**Proof.**

From the definition of $\text{CL}_R$, we see that $\text{Conc}(\mathcal{E}) \subseteq \text{CL}_R(\text{Conc}(\mathcal{E}))$. Let us prove that $\text{CL}_R(\text{Conc}(\mathcal{E})) \subseteq \text{Conc}(\mathcal{E})$. Suppose that $\alpha \in \text{CL}_R(\text{Conc}(\mathcal{E}))$. This means that there exists $\alpha_1, \ldots, \alpha_k \in \text{Conc}(\mathcal{E})$ and that there exists a derivation sequence $F_0, \ldots, F_n$ such that $F_0 = \{\alpha_1, \ldots, \alpha_k\}$ and $\alpha \in F_n$. Note that from Proposition 1, we know that $\{\alpha_1, \ldots, \alpha_k\}$ is $R$-consistent. Since $\alpha_1, \ldots, \alpha_k \in \text{Conc}(\mathcal{E})$ then there exist $\alpha_1, \ldots, \alpha_k \in \mathcal{E}$ such that $\text{Conc}(\alpha_1) = \alpha_1, \ldots, \text{Conc}(\alpha_k) = \alpha_k$. Thus,
there exists an argument $a$ such that $\text{Supp}(a) = \text{Supp}(a_1) \cup \ldots \cup \text{Supp}(a_k)$ and $\text{Conc}(a) = a$. Since $\mathcal{E}_i$ is a preferred, a stable or the grounded extension, Theorems 1 and 2 imply that there exists a set of formulae $S$ such that $\mathcal{E}_i = \text{Arg}(S)$. Consequently, $\mathcal{E}_i = \text{Arg}(\text{Base}(\mathcal{E}_i))$. From this observation and since $\text{Supp}(a) \subseteq \text{Base}(\mathcal{E}_i)$, we conclude that $a \in \mathcal{E}_i$. Thus, $a \in \text{Conc}(\mathcal{E}_i)$, which ends the proof.

In the case of grounded semantics, the result holds directly from the first part of the proposition. The reminder of the proof considers stable or preferred semantics. From the definition of $\text{Cl}_{\mathcal{G}}(\text{Output}_\mathcal{A}(\mathcal{A}F_K)) \subseteq \text{Cl}_{\mathcal{G}}(\text{Output}_\mathcal{A}(\mathcal{A}F_K))$. So we only need to prove that $\text{Cl}_{\mathcal{G}}(\text{Output}_\mathcal{A}(\mathcal{A}F_K)) \subseteq \text{Output}_\mathcal{A}(\mathcal{A}F_K)$.

Let $\alpha \in \text{Cl}_{\mathcal{G}}(\text{Output}_\mathcal{A}(\mathcal{A}F_K))$. Then there exist $a_1, \ldots, a_k \in \text{Output}_\mathcal{A}(\mathcal{A}F_K)$ such that there is a derivation sequence $F_0, \ldots, F_n$ such that $F_0 = \{a_1, \ldots, a_k\}$ and $\alpha \in F_n$. Since $a_1, \ldots, a_k \in \text{Output}_\mathcal{A}(\mathcal{A}F_K)$ then for every $\mathcal{E}_i \in \text{Ext}_\mathcal{A}(\mathcal{A}F_K)$, we have $a_1, \ldots, a_k \in \mathcal{E}_i$. Therefore for every $\mathcal{E}_i \in \text{Ext}_\mathcal{A}(\mathcal{A}F_K), \alpha \in \text{Cl}_{\mathcal{G}}(\text{Conc}(\mathcal{E}_i))$.

From the first part of the proof, $\text{Cl}_{\mathcal{G}}(\text{Conc}(\mathcal{E}_i)) = \text{Conc}(\mathcal{E}_i)$. Thus, for every $\mathcal{E}_i \in \text{Ext}_\mathcal{A}(\mathcal{A}F_K), \alpha \in \text{Conc}(\mathcal{E}_i)$. This means that $\alpha \in \text{Output}_\mathcal{A}(\mathcal{A}F_K)$.

7 Summary and Conclusion

This paper investigates the links between the semantics used in argumentation theory and those from the inconsistent ontological KB query answering.

Contribution of the paper. First, we show that it is possible to instantiate Dung's abstract argumentation theory in a way to deal with inconsistency in an ontological KB. Second, we formally prove the links between the semantics from ontological KB query answering and those from argumentation theory: ICR semantics corresponds to sceptical acceptance under stable or preferred argumentation semantics, AR semantics corresponds to universal acceptance under stable or preferred argumentation semantics and IAR semantics corresponds to acceptance under grounded argumentation semantics. Third, we show that the instantiation we define satisfies the rationality postulates. The fourth contribution of the paper is to make a bridge between the argumentation community and the knowledge representation community in this context, allowing for future exchanges.

Applications of our work. The first possible application of our work is to import some results about semantics and acceptance from argumentation to ontological KB query answering and vice versa. Second, arguments can be used for explanatory purposes. In other words, we can use arguments and counter arguments to graphically represent and explain why different points of view are conflicting or not and why certain argument is (not) in all extensions. However, we suppose that the user understands the notion of logical consequence under first order logic when it comes to consistent data. For example, we suppose that the user is able to understand that if $\text{cat}(\text{Toms}) \land \text{misaw}(\text{Toms})$ is present in the set, then queries $\text{cat}(\text{Toms})$ and $\exists x \text{cat}(x)$ are both true. To sum up, we suppose that the other methods are used to explain reasoning under consistent knowledge and we use argumentation to explain reasoning under inconsistent knowledge.

Related work. Note that this is the first work studying the link between semantics used in argumentation (stable, preferred, grounded) and semantics used in inconsistent ontological knowledge base query answering (AR, IAR, ICR). There is not much related work. However, we review some papers that study similar issues.
For instance, the link between maximal consistent subsets of a knowledge base and stable extensions of the corresponding argumentation system was shown by Cayrol [11]. That was the first work showing this type of connection between argument-based and non argument-based reasoning. This result was generalised [20] by studying the whole class of argumentation systems corresponding to maximal consistent subsets of the propositional knowledge base. The link between the ASPIC system [18] and the Argument Interchange Format (AIF) ontology [13] has recently been studied [7]. Another related paper comprises constructing an argumentation framework with ontological knowledge allowing two agents to discuss the answer to queries concerning their knowledge (even if it is inconsistent) without one agent having to copy all of their ontology to the other [9]. While those papers are in the area of our paper, none of them is related to the study of the links between different semantics for inconsistent ontological KB query answering and different argumentation semantics.

Future work. We plan to answer different questions, like: Can other semantics from argumentation theory yield different results? Are those results useful for inconsistent ontological KB query answering? What happens in the case when preferences are present? What is the link between having preferences on databases and having preferences on arguments? More generally speaking, we want to examine how the knowledge representation community could benefit from other results from argumentation theory and whether the argumentation community could use some open problems in the knowledge representation as inspiration for future work.

Abstract. Conceptual Graphs are a powerful visual knowledge representation language. In this paper we are interested in the use of Conceptual Graphs in the setting of Ontology Based Data Access, and, more specifically, in reasoning in the presence of inconsistency. We present different explanation heuristics of query answering under inconsistency and show how they can be implemented under the Conceptual Graphs editor COGUI.

1 Introduction

We place ourselves in a Rule-based Data Access (RBDA) setting that investigates how to query multiple data sources defined over the same ontology represented using a rule based language. The RBDA is a specific case of the Ontology Based Data Access (OBDA) setting. In RBDA we assume that the ontology is encoded using rules. The growing number of distinct data sources defined under the same ontology makes OBDA an important and timely problem to address. The input to the problem is a set of facts, an ontology and a conjunctive query. We aim to find if there is an answer to the query in the facts (eventually enriched by the ontology).

More precisely, the RBDA problem stated in reference to the classical forward chaining scheme is the following: “Can we find an answer to the query \( Q \) in a database \( F' \) that is built from \( F \) by adding atoms that can be logically deduced from \( F \) and the rule based ontology \( R \)?”

In certain cases, the integration of factual information from various data sources may lead to inconsistency. A solution is then to construct maximal (with respect to set inclusion) consistent subsets of \( F \) called repairs [6, 20]. Once the repairs are computed, there are different ways to combine them in order to obtain an answer for the query.

In this paper we address the RBDA problem from a Conceptual Graphs perspective. Conceptual Graphs are powerful visual formalism for representing a subset of First Order Logic covered by the RBDA setting.

We make explicit these links and focus on the case where we want to perform query answering in presence of inconsistency. We present query answering explanation strategies inspired from the link between the OBDA inconsistent-tolerant semantics and argumentation acceptance semantics[11]. Our work is inspired by the argumentation explanation power [14, 25, 28].
2 Related work

There are two major approaches in order to represent an ontology for the OBDA problem and namely Description Logics (such as $\mathcal{EL}$ [2]) and DL-Lite [9] families) and rule based languages (such as the Datalog$^+$ [8] language, a generalization of Datalog that allows for existentially quantified variables in the head of the rules). When using rules for representing the ontology we would denote the OBDA problem under the name of RBDA. Despite Datalog$^+$ undecidability when answering conjunctive queries, there exist decidable fragments of Datalog$^+$ which are studied in the literature [5]. These fragments generalize the above mentioned Description Logics families.

Here we follow the second method: representing the ontology via rules. We give a general rule based setting knowledge representation language equivalent to the Datalog$^+$ language and show how this language is equivalent to Conceptual Graphs with rules and negative constraints.

Within this language we are mainly interested in studying the question of "why an inconsistent KB entails a certain query $\alpha$ under an inconsistency-tolerant semantics". Indeed, many works focused on the following questions: "Why a concept $C$ is subsumed (non-subsumed) by $D$" or "Why the KB is unsatisfiable and incoherent"? The need for explanation-aware methods stems from the desire to seek a comprehensive means that facilitates maintenance and repairing of inconsistent knowledge bases as well as understanding the underlying mechanism for reasoning services. In the field of databases there has been work on explaining answer and non-answer returned by database systems [1, 24, 23, 16, 15] using causality and responsibility or using a cooperative architecture to provide a cooperative answer for query failing.

In the area of DLs, the question was mainly about explaining either reasoning (subsumption and non-subsumption) or unsatisfiability and incoherence. In a seminal paper McGuinness et al. [22, 7] addressed the problem of explaining subsumption and non-subsumption in a coherent and satisfiable DL knowledge base using formal proofs as explanation based on a complete and sound deduction system for a fragment of Description Logics, while other proposals [27, 26, 3, 4] have used Axiom pinpointing and Concept pinpointing as explanation to highlight contradictions within an unsatisfiable and incoherent DL KB.

Another proposal [19, 18] is the so-called justification-oriented proofs in which the authors proposed a proof-like explanation without the need for deduction rules. The explanation then is presented as an acyclic proof graph that relates axioms and lemmas. Another work [12] in the same context proposes a resolution-based framework in which the explanation is constructed from a refutation graph.

3 Logical Language

We consider a (potentially inconsistent) knowledge base composed of the following:

- A set $F$ of facts that correspond to existentially closed conjunctions of atoms. The atoms can contain $n$-ary predicates. The following facts are borrowed from [21]: $F_1 : \text{directs}(\text{John}, d_1)$, $F_2 : \text{directs}(\text{Tom}, d_1)$, $F_3 : \text{directs}(\text{Tom}, d_2)$, $F_4 : \text{supervises}(\text{Tom}, \text{John})$, $F_5 : \text{works in}(\text{John}, d_1)$, $F_6 : \text{works in}(\text{Tom}, d_1)$.
A set of negative constraints which represent the negation of a fact. Alternatively negative constraints can be seen as rules with the absurd conclusion. Negative constraints can also be n-ary. For example, $N_1 = \forall x, y, z (\text{supervises}(x, y) \land \text{works\_in}(x, z) \rightarrow \bot$ and $N_2 = \forall x, y \text{supervises}(x, y) \land \text{manager}(y) \rightarrow \bot$ are negative constraints.

An ontology composed of a set of rules that represent general implicit knowledge and that can introduce new variables in their head (conclusion). Please note that these variables, in turn, can trigger new rule application and cause the undecidability of the language in the general case. Different rule application strategies (chase), including the skolemized chase, are studied in the literature. For example

\begin{itemize}
  \item $R_1 = \forall x \exists d \text{works\_in}(x, d) \rightarrow \text{emp}(x)$
  \item $R_2 = \forall x \exists d \text{directs}(x, d) \rightarrow \text{emp}(x)$
  \item $R_3 = \forall x \exists d \text{directs}(x, d) \land \text{works\_in}(x, d) \rightarrow \text{manager}(x)$
  \item $R_4 = \forall x \text{emp}(x) \rightarrow \exists y (\text{office}(y) \land \text{uses}(x, y))$
\end{itemize}

A rule is applicable to a set of facts $F$ if and only if the set entails the hypothesis of the rule. If rule $R$ is applicable to the set $F$, the application of $R$ on $F$ produces a new set of facts obtained from the initial set with additional information from the rule conclusion. We then say that the new set is an immediate derivation of $F$ by $R$ denoted by $R(F)$. For example $R_1(F_0) = \text{works\_in}(\text{John}, d_1) \land \text{emp}(\text{John})$.

Let $F$ be a set of facts and let $R$ be a set of rules. A set $F_0$ is called an $R$-derivation of $F$ if there is a sequence of sets (derivation sequence) $(F_0, F_1, \ldots, F_n)$ such that: (i) $F_0 \subseteq F$, (ii) $F_0$ is $R$-consistent, (iii) for every $i \in \{1, \ldots, n-1\}$, it holds that $F_i$ is an immediate derivation of $F_{i-1}$.

Given a set $\{F_0, \ldots, F_k\}$ and a set of rules $R$, the closure of $\{F_0, \ldots, F_k\}$ with respect to $R$, denoted $\text{Cl}_R(\{F_0, \ldots, F_k\})$, is defined as the smallest set (with respect to $\subseteq$) which contains $\{F_0, \ldots, F_k\}$, and is closed for $R$-derivation (that is, for every $R$-derivation $F_i$ of $\{F_0, \ldots, F_k\}$, we have $F_n \subseteq \text{Cl}_R(\{F_0, \ldots, F_k\})$). Finally, we say that a set $F$ and a set of rules $R$ entail a fact $G$ (and we write $F, R \models G$) if the closure of the facts by all the rules entails $F$ (i.e. if $\text{Cl}_R(F) \models G$).

Given a set of facts $\{F_1, \ldots, F_k\}$, and a set of rules $R$, the set of facts is called $R$-inconsistent if and only if there exists a constraint $N = \neg F$ such that $\text{Cl}_R(\{F_1, \ldots, F_k\}) \models \neg F$. A set of facts is said to be $R$-consistent if and only if it is not $R$-inconsistent.

A knowledge base $K = (F, R, N_1, \ldots, N_n)$ composed of a set of facts (denoted by $F$), a set of rules (denoted by $R$) and a set of negative constraints (denoted by $N_1 \ldots N_n$), is said to be consistent if and only if $F$ is $R$-consistent. A knowledge base is inconsistent if and only if it is not consistent.

The above facts $\{F_1, \ldots, F_k\}$ are $R$-inconsistent with $R = \{R_1, \ldots, R_4\}$ since $\{F_1, F_4, F_5\}$ activate together $N_1$. Moreover, $R_3$ can be applied on $F_1$ and $F_2$ delivering the new fact $\text{manager}(\text{John})$ which put together with $F_4$ activate $N_2$.

### 3.1 Conceptual Graphs Representation

Conceptual Graphs are a visual, logic-based knowledge representation. They encode a part of the ontological knowledge in a structure called support. The support consists of a number of taxonomies of the main concepts
(unary predicates) and relations (binary or more predicates) used to describe the world. Note that these taxonomies correspond to certain rules in Datalog. More complex rules (for instance representing transitivity or symmetry of relations) or rules that introduce existential variables in the conclusion are represented using Conceptual Graphs rules. Finally, negative constraints represent rules with the conclusion the absurd operator (or, logically equivalent, negation of facts).

The factual information is described using a bipartite graph in which the two classes of the partition are the concepts, and the relations respectively.

We recall the definition of support and fact following [10]. We consider here a simplified version of a support \( S = (T_C, T_R, I) \), where: \((T_C, \leq_s)\) is a finite partially ordered set of concept types; \((T_R, \leq_r)\) is a partially ordered set of relation types, with a specified arity; \(I\) is a set of individual markers. A (simple) CG is a triple CG= \([S, G, \lambda]\), where:

- \(S\) is a support;
- \(G = (V_C, V_R, E)\) is an ordered bipartite graph; \(V = V_C \cup V_R\) is the node set of \(G\), \(V_C\) is a finite nonempty set of concept nodes, \(V_R\) is a finite set of relation nodes; \(E\) is the set of edges \(\{v, v\}_e\) where the edges incident to each relation node are ordered and this ordering is represented by a positive integer label attached to the edge; if the edge \(\{v, v\}_e\) is labeled \(i\) in this ordering then \(v_e\) is the \(i\)-neighbor of \(v\), and is denoted by \(N^i_C(v)\);
- \(\lambda : V \rightarrow S\) is a labeling function; if \(v \in V_C\) then \(\lambda(v) = (\text{type}_v, \text{ref}_v)\) where \(\text{type}_v \in T_C\) and \(\text{ref}_v\) \(\in I\) \(\cup \{\ast\}\); if \(v \in V_R\) then \(\lambda(v) \in T_R\).

We denote a conceptual graph CG= \([S, G, \lambda]\) by \(G\), keeping support and labeling implicit. The order on \(\lambda(v)\) preserves the (pair-wise extended) order on \(T_C\) (\(T_R\)), considers \(I\) elements mutually incomparable, and \(s \geq i\) for each \(i \in I\). Usually, CGs are provided with a logical semantics via the function \(\Phi\), which associates to each CG a FOL formula (Sowa 1984). If \(S\) is a support, a constant is associated to each individual marker, a unary predicate to each concept type and a \(n\)-ary predicate to each \(n\)-ary relation type. We assume that the name for each constant or predicate is the same as the corresponding element of the support. The partial orders specified in \(S\) are translated in a set of formulae \(\Phi(S)\) by the following rules: if \(t_1, t_2 \in T_C\) such that \(t_1 \leq t_2\), then \(\forall x(t_2(x) \rightarrow t_1(x))\) is added to \(\Phi(S)\); if \(t_1, t_2 \in T_R\), have arity \(k\) and \(t_1 \leq t_2\), then \(\forall x_1, x_2, \ldots, x_k(t_2(x_1, x_2, \ldots, x_k) \rightarrow t_1(x_1, x_2, \ldots, x_k))\) is added to \(\Phi(S)\).

If CG= \([S, G, \lambda]\) is a conceptual graph then a formula \(\Phi(CG)\) is constructed as follows. To each concept vertex \(v \in V_C\) a term \(a_v\) and a formula \(\phi(v)\) are associated: if \(\lambda(v) = \{\text{type}_v, \ast\}\) then \(a_v = x_v\) (a logical variable) and if \(\lambda(v) = \{\text{type}_v, i_v\}\), then \(a_v = i_v\) (a logical constant); in both cases, \(\phi(v) = \text{type}_v(a_v)\). To each relation vertex \(r \in V_R\), with \(\lambda(r) = \text{type}_r\) and \(\text{deg}_r = k\), the formula associated is \(\phi(r) = \text{type}_r(a_{N^1_C(v)}, \ldots, a_{N^*_C(v)}))\).

\(\Phi(CG)\) is the existential closure of the conjunction of all formulas associated with the vertices of the graph. That is, if \(V_C(\ast) = \{v_1, \ldots, v_n\}\) is the set of all concept vertices having generic markers, then \(\Phi(CG) = \exists x_1 \ldots \exists x_p(\land_{v \in V_C(\ast)} \phi(v))\).

If \((G, \lambda_G)\) and \((H, \lambda_H)\) are two CGs (defined on the same support \(S\)) then \(G \geq H\) (\(G\) subsumes \(H\)) if there is a projection from \(G\) to \(H\). A projection is a mapping \(\pi\)
from the vertices set of $G$ to the vertices set of $H$, which maps concept vertices of $G$ into concept vertices of $H$, relation vertices of $G$ into relation vertices of $H$, preserves adjacency (if the concept vertex $v$ in $V_G^C$ is the $i$th neighbour of relation vertex $r$ in $V_G^R$ then $\pi(v)$ is the $i$th neighbour of $\pi(r)$) and furthermore $\lambda_H(x) \geq \lambda_H(\pi(x))$ for each vertex $x$ of $G$. If $G \geq H$ then $\Phi(S), \Phi(H) \models \Phi(G)$ (soundness). Completeness (if $\Phi(S), \Phi(H) \models \Phi(G)$ then $G \geq H$) only holds if the graph $H$ is in normal form, i.e. if each individual marker appears at most once in concept node labels.

A CG rule $(\text{Hyp}, \text{Conc})$ expresses implicit knowledge of the form “if hypothesis then conclusion”, where hypothesis and conclusion are both basic graphs. This knowledge can be made explicit by applying the rule to a specific fact: intuitively, when the hypothesis graph is found in a fact, then the conclusion graph can be added to this fact. There is a one to one correspondence between some concept nodes in the hypothesis with concept nodes in the conclusion. Two nodes in correspondence refer to the same entity. These nodes are said to be connection nodes. A rule can be represented by a bicolored graph or by a pair of two CGs (represented, for instance, on the right and respectively left hand side of the screen).

A rule $R$ can be applied to a CG $H$ if there is a homomorphism from its hypothesis to $H$. Applying $R$ to $H$ according to such a homomorphism $\pi$ consists of “attaching” to $H$ the conclusion of $R$ by merging each connection node in the conclusion with the image by $\pi$ of the corresponding connection node in the hypothesis. When a knowledge base contains a set of facts (say $F$) and a set of rules (say $R$), the query mechanism has to take implicit knowledge coded in rules into account. The knowledge base answers a query $Q$ if a CG $F'$ can be derived from $F$ using the rules of $R$ such that $Q$ maps to $F'$.

We note that using the $(F, R, N)$ Datalog notation or the rule based Conceptual Graphs with negative constraints has the same logical expressivity. However, the added value of using Conceptual Graphs comes from the visual depiction of the knowledge. This aspect is shown next, where the previous example knowledge base is depicted using COGUI, a Conceptual Graphs editor developed by the LIRMM, University of Montpellier 2.

### 3.2 COGUI CG Editor

All figures depict graphs drawn using the conceptual graph editor CoGui. CoGui is a Conceptual Graphs editor. Please note that CoGui is also fully integrated with the conceptual graph engine Cogitant to perform reasoning on the above mentioned graphs.

Let us consider again the knowledge base previously considered:

- $F_1 : \text{directs}(\text{John}, d_1), F_2 : \text{directs}(\text{Tom}, d_2), F_3 : \text{supervises}(\text{Tom}, \text{John}), F_4 : \text{works_in}(\text{John}, d_1), F_5 : \text{works_in}(\text{Tom}, d_1)$. 
- $N_1 = \forall x, y, z (\text{supervises}(x, y) \land \text{work_in}(x, z) \land \text{directs}(y, z)) \rightarrow \bot$ and $N_2 = \forall x, y \text{supervises}(x, y) \land \text{manager}(y) \rightarrow \bot$.

- The set of rules: 
  - $R_1 = \forall x, y \text{work_in}(x, d) \rightarrow \text{emp}(x)$
  - $R_2 = \forall x, y \text{directs}(x, d) \rightarrow \text{emp}(x)$

1 [http://www.lirmm.fr/cogui/](http://www.lirmm.fr/cogui/)

$R_3 = \forall x \forall d \text{directs}(x,d) \land \text{works}\_\text{in}(x,d) \rightarrow \text{manager}(x)$

$R_4 = \forall x \text{emp}(x) \rightarrow \exists y \text{office}(y) \land \text{uses}(x,y)$

Figure 1 presents the concept type hierarchy, the relation type hierarchy and the list of individuals. Please note that the rule hierarchy encodes the rules $R_1$ and $R_2$.

Rules $R_3$ and $R_4$ respectively are depicted in Figure 2. The negative constraints $N_1$ and $N_2$ are depicted in Figure 3.

Finally, the set of facts is represented in Figure 4.
4 Dealing with inconsistency

We recall the definition of inconsistency. Given a set of facts \( \{ F_1, \ldots, F_k \} \), and a set of rules \( \mathcal{R} \), the set of facts is called \( \mathcal{R}\)-inconsistent if and only if there exists a constraint \( N = \neg\mathcal{F} \) such that \( \mathcal{G}_\mathcal{R}(\{ F_1, \ldots, F_k \}) \models \mathcal{F} \).

In Figure 5 we can see that there is a negative constraint entailed by the facts enriched by the rules. The image of the negative constraint by homomorphism is represented in red (if color is available) or darker shade of grey (grayscale).

Like in classical logic everything can be entailed from an inconsistent knowledge base. Different semantics have been introduced in order to allow query answering in the presence of inconsistency. Here we only focus on the ICR (Intersection of Closed Repair) semantics defined as follows:
Definition 1. Let \( K = (F, \mathcal{R}, \mathcal{N}) \) be a knowledge base and let \( \alpha \) be a query. Then \( \alpha \) is ICR-entailed from \( K \), written \( K \models_{ICR} \alpha \) if and only if \( \bigcap_{A' \in \text{repair}(K)} \text{Cl}_R(A') \models \alpha \).

In the above example, we obtain 6 repairs. The following are one of them (closed under set of rules):

\[
A_1 = \{\text{directs}(John, d_1), \text{directs}(Tom, d_1), \text{directs}(Tom, d_2), \text{supervises}(Tom, John), \text{emp}(John), \text{emp}(Tom), \exists y \text{ (office}(y_1) \land \text{uses}(Tom, y_1)), \exists y \text{ (office}(y_2) \land \text{uses}(John, y_2))\}
\]

The intersection of the closed repairs is:

\[
\bigcap_{A' \in \text{repair}(K)} \text{Cl}_R(A') = \{\text{directs}(Tom, d_1), \text{directs}(Tom, d_2), \text{emp}(Tom), \exists y \text{ uses}(Tom, y), \exists y \text{ office}(y)\}.
\]

Another possibility to deal with an inconsistent knowledge base in the OBDA setting is to define an instantiation [11] of Dung’s abstract argumentation theory [13]. An argumentation framework is composed of a set of arguments and a binary relation defined over arguments, the attack.

Definition 2 (Argument). [11] An argument \( A \) in a knowledge base \( K = (F, \mathcal{R}, \mathcal{N}) \) is a tuple \( A = (F_0, \ldots, F_n) \) where:

- \( (F_0, \ldots, F_{n-1}) \) is a derivation sequence w.r.t \( K \).
- \( F_n \) is an atom, a conjunction of atoms, the existential closure of an atom or the existential closure of a conjunction of atoms such that \( F_{n-1} \models F_n \).

We can extract from each argument its sub-arguments.

Definition 3 (Sub-argument). Let \( K = (F, \mathcal{R}, \mathcal{N}) \) be a knowledge base and \( A = (F_0, F_1, \ldots, F_n) \) be an argument. \( A' = (F_0, \ldots, F_k) \) with \( k \in \{0, \ldots, n - 1\} \) is a sub-argument of \( A \) if (i) \( A' = (F_0, \ldots, F_k) \) is an argument and (ii) \( F_k \in F_{k+1} \).

Let \( A = (F_0, \ldots, F_n) \) be an argument, then \( \text{Supp}(A) = F_0 \) and \( \text{Conc}(A) = F_n \).

Let \( S \subset F \) a set of facts, \( \text{Arg}(S) \) is defined as the set of all arguments \( A \) such that \( \text{Supp}(A) \subseteq S \).
An argument corresponds to a rule derivation. Therefore we can use the Cogui editor in order to depict arguments (via the depiction of rule derivations). In Figure 6 an example of a derivation is depicted. The added information by the rule is visible due to the changed color (pink in color, darker shade of grey on grey scale).

Fig. 6: Visualisation of a rule derivation using CoGui

**Definition 4 (Attack).** [11] Let $K = (F, R, N)$ be a knowledge base and let $a, b \in A$. The argument $a$ attacks $b$, denoted by $(a, b) \in \text{Att}$, iff there exists $\varphi \in \text{Supp}(b)$ such that the set $\{\text{Conc}(a), \varphi\}$ is $R$-inconsistent.

**Definition 5 (Argumentation framework).** [11] Let $K = (F, R, N)$ be a knowledge base, the corresponding argumentation framework $AF_K$ is a pair $(\mathcal{A} = \text{Arg}(F), \text{Att})$ where $\mathcal{A}$ is the set of arguments that can be built from $F$ and $\text{Att}$ is the attack relation.

Let $E \subseteq \mathcal{A}$ and $a \in \mathcal{A}$.

- We say that $E$ is conflict free iff there exists no arguments $a, b \in E$ such that $(a, b) \in \text{Att}$.
- $E$ defends $a$ iff for every argument $b \in \mathcal{A}$, if we have $(b, a) \in \text{Att}$ then there exists $c \in E$ such that $(c, b) \in \text{Att}$.
- $E$ is admissible iff it is conflict free and defends all its arguments.
- $E$ is a preferred extension iff it is maximal (with respect to set inclusion) admissible set.
- $E$ is a stable extension iff it is conflict-free and $\forall a \in \mathcal{A}\setminus E$, there exists an argument $b \in E$ such that $(b, a) \in \text{Att}$.
- $E$ is a grounded extension if it is complete extension.

We denote by $\text{Ext}(AF_K)$ the set of extensions of $AF_K$. We use the abbreviations $p, s,$ and $g$ for respectively preferred, stable and grounded semantics. An argument is skeptically accepted if it is in all extensions, credulously accepted if it is in at least one extension and rejected if it is not in any extension.

The following results are then showed by [11]:

145
Theorem 1. [11] Let $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ be a knowledge base, let $\mathcal{AF}_K$ be the corresponding argumentation framework, $\alpha$ be a query, and $x \in \{s, p\}$ be stable or preferred semantics. Then $\mathcal{K} \models_{ICR} \alpha$ iff $\alpha$ sceptically accepted under semantics $x$.

5 Argumentative Explanation

In this section we define two different heuristics for explanation of inconsistency tolerant semantics. Since these heuristics work under inconsistent knowledge bases the Cogui editor is not yet adapted to implement them. We note that explanations correspond to the notion of argument, thus, the Cogui visual power could be easily adapted for our case. Moreover, in section 5.1 we show the equivalence between one type of explanation and a visual rule depiction in Cogui. This could be a starting point for the explanation of queries under inconsistency using Cogui.

When handling inconsistent ontological knowledge bases we are interested in the explanation of query answers conforming to a given semantics. More precisely we are interested in explaining why a query $\alpha$ is ICR-entailed by an inconsistent knowledge base $\mathcal{K}$. By explanation we mean a structure that has to incorporate minimal set of facts (w.r.t $\subseteq$) and general rules that, if put together, will lead to the entailment of the query $\alpha$. According to this intuition (which coincides with the definition of [17]) and the link between inconsistent ontological knowledge bases and logic-based argumentation framework, a first candidate of explanation is an argument. However, an argument as defined in definition 2 can be cumbersome and difficult to understand, because the information of how these derivations have been achieved and how they lead to the conclusion are missing. Therefore we propose a refined explanation that incorporates rules as a crucial component.

Definition 6 (Explanation). Let $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ be an inconsistent knowledge base, let $\alpha$ be query and let $\mathcal{K} \models_{ICR} \alpha$. An explanation for $\alpha$ in $\mathcal{K}$ is a 3-tuple $E = (A, G, C)$ composed of three finite sets of formulae such that: (1) $A \subseteq \mathcal{F}$, $G \subseteq \mathcal{R}$, (2) $C \VDash \alpha$, (3) $\text{Cl}_G(A) \not\Vdash \bot$ (consistency), (4) For every formula $\beta$ in $A$, $\text{Cl}_G(A - \beta) \not\Vdash C$ (minimality). Such that $\text{Cl}_G$ represents the closure w.r.t to the set of rules $G$.

We denote by $\mathcal{EXP}$ the universe of explanations and by $\mathcal{EXP}_\alpha$ the set of all explanations for $\alpha$. We denote the sets $A$, $G$ and $C$ as antecedents, general laws and conclusions respectively. Here the definition specifies three important components for explaining query $\alpha$. First, the set $A$ of antecedent conditions which is a minimal subset of facts that entails the query $\alpha$. Second, the set of general laws $G$ (from now on, rules) that produce the query $\alpha$, the reason for integrating rules is that the user is often interested in knowing how we achieved the query. Finally, the third component is the conclusion $C$ (the answer for the query $\alpha$). The definition also imposes a central concept, namely explanation consistency.

An explanation can be computed directly from $\mathcal{K}$ or from an argumentation framework using the following mapping $h$.

Definition 7 (Mapping $h$). Given an inconsistent knowledge base $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ and $\mathcal{AF}_K = (A, Att)$ the corresponding argumentative framework. The mapping $h$ is a total function defined on $A \rightarrow \mathcal{EXP}$ as $E = h((F_0, ..., F_n))$ with:
- The set of antecedent conditions $A = F_0$.
- The set of rules $G \subseteq R$, such that $\forall r \in R, r \in G$ iff for all $F_i$ in $x$ the rule $r$ is applicable to $F_i$.
- The conclusion $C = F_n$ iff $\text{CIF}(A) \models F_n$.

Proposition 1 (Bijection of $\mathcal{A}$). For any argument $a \in \mathcal{A}$, the mapping $\mathcal{A}$ is a bijection.

The proposition follows from the definition of the mapping because for every argument we can construct one explanation. Since the mapping is a bijection, we call the argument $x_a = \mathcal{A}^{-1}(e)$ the corresponding argument of an explanation $e$. We say the argument $x_a$ supports the explanation $e$. The following proposition states that there is always an explanation for an ICR-entailed query.

Proposition 2 (Existence of explanation). For every query $\alpha$ such that $\mathcal{K} \models_{\text{ICR}} \alpha$, the set $\mathcal{E} \mathcal{X} \mathcal{P}_\alpha$ is not empty.

Proof 1 On the one hand, if $\mathcal{K} \models_{\text{ICR}} \alpha$, then the query $\alpha$ is sceptically accepted. That means $\forall E \in \text{Ext}(\mathcal{K}) \mathcal{E} \models \alpha$. Hence there is an argument $a \in \mathcal{E}$ such that Cons$(a) \models \alpha$. On the other hand, using the mapping $\mathcal{A}$ we have $e = \mathcal{A}(a)$ is an explanation for $\alpha$, namely $e \in \mathcal{E} \mathcal{X} \mathcal{P}_\alpha$. Consequently $\mathcal{E} \mathcal{X} \mathcal{P}_\alpha \neq \emptyset$

Example 1 (Corresponding Argument). Let us explain $\alpha = \exists x \text{ emp}(x)$. We can build the following argument for $\alpha$:

$$a^*_\alpha = \{(\text{works}_\alpha(Tom, d_1)), \{\text{works}_\alpha(Tom, d_1), \text{emp}(Tom)\}, \text{emp}(Tom)),$$

and the delivered explanation is:

$$E_a = \{(\text{directs}(Tom, d_1)), \{\forall x \forall d \text{ works}_\alpha(x, d) \rightarrow \text{emp}(x)\}, \text{emp}(Tom))\}.$$

5.1 Deepened Explanation (d-explanation)

Definition 8 (d-explanation). Let $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ be an inconsistent knowledge base, let $\alpha$ be a query and let $\mathcal{K} \models_{\text{ICR}} \alpha$. Then, the finite sequence of tuples $d = (t_1, t_2, ..., t_n)$ is a d-explanation for $\alpha$ iff:

1. For every tuple $t_i = (a_i, r_i) \in d$ such that $i \in \{1, ..., n\}$, it holds that $a_i \subseteq \text{CIF}(\mathcal{F})$ and $r_i \in \mathcal{R}$.
2. For every tuple $t_i = (a_i, r_i) \in d$ such that $i \in \{2, ..., n\}$ we have $a_i = a_i' \cup a_i''$ where (i) $r_{i-1}(a_{i-1}) \models a_i'$, (ii) $a_i'' \subseteq \text{CIF}(\mathcal{F})$ and (iii) $r_i$ is applicable to $a_i$. Note that if $i = 1$ then $a_i' = \emptyset$.
3. The tuple $(a_n, r_n)$ entails $\alpha$ (i.e $r_n(a_n) \models \alpha$).
We denote by $\mathcal{D}$ the universe of $d$-explanations and by $\mathcal{D}_{\alpha}$ the set of all $d$-explanations for a query $\alpha$.

The intuition about the $d$-explanation $d$ is as follows: tuples in $d$ represent the rule (fact, applicable rule), and the sequence of tuples represents the order by which we achieve the answer of the query. Think of it as a chain where each $a$ has a link with the previous $a_{i-1}$ through the rule $r_{i-1}$. This is similar to the notion of derivation depicted in Figure 6.

Example 2 (Deepened explanation). The deepened explanation associated to $\alpha$ is the same as $E$ and doesn’t provide more information. Let us consider the explanation of $\alpha_2 = \exists x \text{office}(x)$. A possible argument for $\alpha_2$ is:

$\alpha_{2i} = \{ \{ \text{works}_{\text{in}}(\text{Tom}, d_1) \}, \{ \text{works}_{\text{in}}(\text{Tom}, d_1) \}, \{ \text{emp}(\text{Tom}) \}, \exists y (\text{office}(y) \land \text{uses}(\text{Tom}, y)) \},$ $\exists y (\text{office}(y) \land \text{uses}(\text{Tom}, y))$.

So $E_{2i} = \{ \{ \text{works}_{\text{in}}(\text{Tom}, d_1) \}, \{ \forall x \exists y \text{directs}(x, d) \rightarrow \text{emp}(x), \forall x \text{emp}(x) \rightarrow \exists y (\text{office}(y) \land \text{uses}(x, y)) \} \}, \exists y (\text{office}(y) \land \text{uses}(x, y))$).

$D_E = \{ \{ \text{works}_{\text{in}}(\text{Tom}, d_1) \}, \forall x \exists y \text{directs}(x, d) \rightarrow \text{emp}(x), \text{emp}(\text{Tom}), \forall x \text{emp}(x) \rightarrow \exists y (\text{office}(y) \land \text{uses}(x, y)) \}$.

There is a bijection between an explanation $e$ and a $d$-explanation $d$ represented here by the following mapping.

Definition 9 (Mapping $D$). Let $K = (F, R, N)$ be an inconsistent knowledge base, $\alpha$ be a query, $e = (A, G, C) \in EXP$ be an explanation for $\alpha$ and $d = (t_1, t_2, ..., t_n) \in \mathcal{D}$ be a $d$-explanation for $\alpha$. The mapping $D$ is total function $\mathcal{D} : EXP \rightarrow \mathcal{D}$, $e \rightarrow d$ defined as follows:

1. For every tuple $t_i = (a_i, r_i)$ such that $i \in \{1, ..., n\}$, it holds that $r_i \in G$.
2. For every tuple $t_i = (a_i, r_i)$ in $D$ such that $i \in \{2, ..., n\}$ we have $a_i = a'_i \cup a''_i$ where $r_{i-1}(a_{i-1}) \models a'_i$, $a''_i \subset A$ and $r_i$ is applicable to $a_i$. Note that if $i = 1$ then $a_1 = A$ and $r_1$ is applicable to $a_1$.
3. The tuple $(a_i, r_i)$ entails $\alpha$ (i.e $r_{n}(a_n) \models \alpha$) and $C \models \alpha$.

Since the mapping is a bijection the existence of the inverse function is guaranteed. Thereby we consider the mapping $\mathcal{D}(e)$ as deepening the explanation $e$ and the inverse mapping $\mathcal{D}^{-1}(d)$ as simplifying the $d$-explanation $d$. The advantage of such a mapping is that it gives the users the freedom to shift from an explanation to another which complies better with their level of understanding and their experiences. Also it guarantees that every explanation can be deepened. As done before, we also define the corresponding argument $x_d$ for a $d$-explanation $d$, as the corresponding argument $x_e$ for an explanation $e = D^{-1}(d)$. This can be achieved by the following composition of function: $x_d = (D \circ \Phi)^{-1}(d)$.

6 Conclusion

In this paper we have presented an argumentative approach for explaining user query answers in a particular setting. Namely, an inconsistent ontological knowledge base
where inconsistency is handled by inconsistency-tolerant semantics (ICR) and it is is-
sued from the set of facts. In this paper we have exploited the relation between onto-
tological knowledge base and logical argumentation framework to establish different
levels of explanation ranging from an explanation based on the notion of argument to
a user-invoked explanation called deepened explanation. We have also shown the rela-
tion between every type of explanation using a one-to-one correspondence which gives
the user the possibility to deepen (or simplify) the explanation in hand. Future works
aims at studying the proposed explanation in the context of other inconsistency-tolerant
semantics. We are currently working on a Cogui based plug-in that only deals with
reasoning under inconsistency and the above mentioned semantics.

ABSTRACT

Within the framework of the European project EcoBioCap, we model a real world use case aiming at conceiving the next generation of food packagings. The objective is to select packaging materials according to possibly conflicting requirements expressed by the involved parties (food and packaging industries, health authorities, consumers, waste management authority, etc.). The requirements and user preferences are modeled by several ontological rules provided by the stakeholders expressing their viewpoints and expertise. Since several aspects need to be considered (CO2 and O2 permeance, interaction with the product, sanitary, cost, end of life, etc.) in order to select objects, an argumentation process can be used to express/reason about different aspects or criteria describing the packagings. We define then in this paper an argumentation approach which combines a description logic (DLR-Lite) within ASPIC framework for relational database querying. The argumentation step is finally used to express and/or enrich a bipolar query employed for packaging selection.

Categories and Subject Descriptors

D.2.11 [Software Engineering]: Software Architecture

Keywords

Argumentation; decision support system; description logics and DLR-Lite; application within the EcoBioCap project.

1. INTRODUCTION

Within the framework of the European project EcoBioCap (www.ecobiocap.eu) about the design of next generation packagings using advanced composite structures based on constituents derived from the food industry, we aim at developing a Decision Support System (DSS) for packaging material selection. The DSS will consist of two steps: (1) aggregating possibly conflicting needs expressed by several parties involved in the considered field and (2) querying a database of packagings with the resulting aggregation obtained at point (1). The problem at hand does not simply consist in addressing a multi-criteria optimization problem [4]: the domain experts would need to be able to justify why a certain packaging (or set of possible packagings) are chosen. Argumentation theory in general [8, 3, 11] is actively pursued in the literature, some approaches even combining argumentation and multi criteria decision making [2].

We rely in this work on a logical structured argumentation system [1, 10, 9] since it (i) allows the expression of logical arguments as a combination of facts and inference rules, (ii) defines attacks and defeat relations between arguments based on a logical conflict notion. Stakeholder’s set of arguments is then modeled as concepts, facts and rules to build a partial knowledge bases $K_1 \ldots$ $K_n$. The union of every stakeholder knowledge base $K = \bigcup_{i=1}^{n} K_i$ will be used to instantiate the ASPIC [1] argumentation system. The solution developed in this paper is to instantiate for each criterion, called viewpoint or aspect, an argumentation system to reason about arguments solely expressed on it. This will then be used to generate the query on the packaging database. The main contribution of this paper is to demonstrate the use of argumentation in a real world industrial scenario within the EcoBioCap project. To this aim we show how to instantiate ASPIC with the DLR-Lite logic modeling expert ontologies in this real world scenario.

2. CONTRIBUTIONS

The main contributions of the paper are the following:

1. A DLR-Lite [7, 5] ontology extended to a negation to express stakeholders’ arguments about packaging characteristics as combination of concepts (defined as m-ary relations connected to a database) and inference rules (specified as subsumptions). The language is detailed in the technical report [12],

2. An instantiation of ASPIC argumentation system AS	 with the proposed DLR-Lite logical language. The instantiated ASPIC AS satisfies the rationality postulates [6], please see details in [12],

3. The study of the influence of the modeling rules on the argumentation results. We showed the limitation of the crisp split of the inference rules into defeasible and strict, and we propose to overcome this limitation a viewpoint approach in which arguments are gathered according to packaging aspects. Each viewpoint delivers subsets of non-conflicting arguments supporting or
We have proposed an argumentation system in which each criterion is considered as a viewpoint in which stakeholders express their arguments in homogenous way. The set of non conflicting viewpoints are then gathered according goals, to form consistent collections which support/oppose them.

We plan to extend the proposed approach to fuzzy argumentation to make it possible to deal with vague and uncertain concepts and rules by exploiting the fuzzy interpretation of the fuzzy DLR-Lite. Another line to develop consists of studying the bipolarity in our context of argumentation.

4. ACKNOWLEDGEMENTS

The research leading to these results has received funding from the European Community’s seventh Framework Program (FP7/2007-2013) under the grant agreement n°FP7-265669-EcoBioCAP project. The authors would like to thank Pr. Leila Amgoud (IRIT Toulouse, CNRS) for her valuable comments and feedback.

Abstract. Within the framework of the European project EcoBioCap (ECOefficient BIOdegradable Composite Advanced Packaging), we model a real-world use case aiming at conceiving the next generation of food packagings. The objective is to select packaging materials according to possibly conflicting requirements expressed by the involved parties (food and packaging industries, health authorities, consumers, waste management authority, etc.). The requirements and user preferences are modeled by several ontological rules provided by the stakeholders expressing their viewpoints and expertise. To deal with these several aspects ($\text{CO}_2$ and $\text{O}_2$ permeance, interaction with the product, sanitary, cost, end of life, etc.) for packaging selection, an argumentation process has been introduced.

1 Introduction

Within the framework of the European project EcoBioCap (www.ecobiocap.eu) about the design of next generation packagings using advanced composite structures based on constituents derived from the food industry, we aim at developing a Decision Support System (DSS) to help parties involved in the packaging design to make rational decisions based on knowledge expressed by the experts of the domain.

The DSS is made of two parts, as depicted in Figure 1:

1. a flexible querying process which is based on a bipolar approach dealing with imprecise data \[8\] corresponding to the characteristics related to the food product to pack like the optimal permeance, the dimension of the packaging, its shape, etc.,
2. an argumentation process which aims at aggregating several stakeholders (researchers, consumers, food industry, packaging industry, waste management policy, etc.) requirements expressed as simple textual arguments, to enrich the querying process by stakeholders’ justified preferences. Each argument supports/opposes a choice justified by the fact that it either meets or not a requirement according to a particular aspect of the packagings.

We implemented of the second part of the DSS, called argumentation system, which aims at aggregating preferences associated with justifications expressed by stakeholders about the characteristics of a packaging. This module
has as inputs stakeholders’ arguments supporting or opposing a packaging choice which could be seen as preferences combined with their justifications, and returns consensual preferences which may be candidates to enrich the bipolar querying system.

The DSS consists of two steps: (i) aggregating possibly conflicting needs expressed by the involved several parties (ii) querying a database of packagings with the resulting aggregation obtained at point (i).

In this real case, packagings have to be selected according to several aspects or criteria (permeance, interaction with the packed food, end of life, etc.), highlighted by the expressed stakeholders’ arguments. The problem at hand does not simply consist in addressing a multi-criteria optimization problem [4]: the domain experts would need to be able to justify why a certain packaging (or set of possible packagings) are chosen. Argumentation theory in general [9, 3, 11] is actively pursued in the literature, some approaches even combining argumentation and multi-criteria decision making [9].

2 Approach

Stakeholder’s set of arguments is then modeled as concepts, facts and rules to build a partial knowledge bases $K_i$. The union of every stakeholder knowledge base $K = \bigcup_{i=1}^{n} K_i$ will be used to instantiate the ASPIC [1] argumentation system, as shown on Figure 2.

The main salient points of our work in the EcoBioCap project are the following:

1. A DLR-Lite [7, 5] ontology extended to a negation to express stakeholders’ arguments about packaging characteristics as combination of concepts.

Fig. 1. Global insight of the EcoBioCap DSS.
(defined as $m$-ary relations connected to a database) and inference rules (specified as subsumptions). The language is detailed in the technical report [12],

2. An instantiation of ASPIC argumentation system ($\text{AS}$) with the proposed DLR-Lite logical language. The instantiated ASPIC $\text{AS}$ satisfies the rationality postulates [6], please see details in [12],

3. The study of the influence of the modeling rules on the argumentation results. We showed the limitation of the crisp split of the inference rules into defeasible and strict, and we propose to overcome this limitation a viewpoint approach in which arguments are gathered according to packaging aspects. Each viewpoint delivers subsets of non-conflicting arguments supporting or opposing a kind of packaging according to a single aspect (shelf life parameters, cost, materials, sanitary, end elf life, etc.),

4. The use of the argumentation results for a bipolar querying of the packaging database. Indeed, we can gather the results onto positive and negative collections. We can then deduce automatically such queries from the collections the users formed during the argumentation process.

5. Implementation of the approach. A java GXT/GWT web interface was developed and a open version is accessible on http://pfl.grignon.inra.fr/EcoBioCapProduction/.
3 Architecture of the argumentation system

As illustrated in Figure 3, the proposed argumentation system relies on 5 main modules, described below.

---

*Argument formalization module:* this module implements a user-friendly interface for a semi-automatic translation of text arguments into a formal representation made of concepts and rules (claims and hypothesis). A graphical representation of the expressed rules is also built as the users formalize their text arguments. The formal representation obtained is finally saved in a database for a persistent storage allowing to reload argumentation projects without rebuilding all the arguments and to reuse also the already formatted rules in other projects.

*Logical arguments:* this module receives as inputs the list of concepts and rules corresponding to text arguments. This list can be the result of the formalization module or given by the user as an XML file. Then, by a derivation process, this module builds all possible arguments according to the logical process defined in ASPIC/ASPIC+ logic-based argumentation frameworks [1, 10] and reused in [13, 14]. This module also exports the argument list into an XML document.

*Conflicts and attacks:* this module relies on the logical arguments built by the previous module. According to the negation operator, it detects all the conflicts among arguments and models them as attacks with respect to the definition of attacks introduced in [13, 14]. The output of this module is an argumentation graph made of arguments (nodes) and attacks (edges).

*Extensions:* an extension is a subset of non-conflicting (consistent) arguments which defend themselves from attacking arguments. The computation of extensions is made under one semantics (preferred, stable, grounded, etc.) as defined in [9]. This module allows the computation of one or all semantics considered (preferred, stable, grounded, eager, semi-stable). We notice that...
theoretically we can get empty extensions under any semantics. This situation occurs when a user expresses at least one self-defeated argument, which is not attacked by any other argument, but attacks all the others. This kind of arguments are called contaminating arguments [15]. The current version of the system detects the rules leading to such arguments and discards them before performing the process of extension computations.

– Extraction of the justified preferences: the computation of extensions delivers one or several extensions. In the case of several extensions, the system lets the users selecting the more suitable one according to their objectives. The selected extension is then used to extract corresponding preferences underlying the contained concepts. These preferences are expressed as a list of couples \((attribute, value)\), where \(attribute\) stands for a packaging attribute as defined in the packaging database schema of the flexible querying system part of the DSS, and \(value\) is the preferred value expressed for the considered attribute.

4 Conclusion

We applied an argumentation approach on a real use case from the industry allowing stakeholders to express their preferences and providing the system with stable concepts and subsumptions of a domain. We have proposed an argumentation system in which each criterion (attribute or aspect) is considered as a viewpoint in which stakeholders express their arguments in homogenous way. Each viewpoint delivers extensions supporting or opposing certain choices according one packaging aspect, which are then used in the querying process. The approach is implemented as freely accessible web application.

c Abstract
d
Evaluating food quality is a complex process since it relies on numerous criteria historically grouped into four main types: nutritional, sensorial, practical and hygienic qualities. They may be completed by other emerging preocupations such as the environmental impact, economic phenomena, etc. However, all these aspects of quality and their various components are not always compatible and their simultaneous improvement is a problem that sometimes has no obvious solution, which corresponds to a real issue for decision making. This paper proposes a decision support method guided by the objectives defined for the end products of an agrifood chain. It is materialized by a backward chaining approach based on argumentation.

Keywords: decision support, knowledge representation, argumentation, reverse engineering, backward chaining, agrifood chain control, goal, viewpoint

Preprint submitted to Ecological Informatics May 25, 2014
1. Introduction

In agrifood chains, the products traditionally go through the intermediate stages of processing, storage, transport, packaging and reach the consumer (the demand) from the producer (the supply). More recently, due to an increase in quality constraints, several parties are involved in production process, such as consumers, industrials, health and sanitary authorities, etc. expressing their requirements on the final product as different point of views which could be conflicting. The notion of reverse engineering control, in which the demand (and not the supply) sets the specifications of desired products and it is up to the supply to adapt and find its ways to respond, can be considered in this case.

In this article, we discuss two aspects of this problem. First, we accept the idea that specifications cannot be established and several complementary points of view - possibly contradictory - can be expressed (nutritional, environmental, taste, etc.). We then need to assess their compatibility (or incompatibility) and identify solutions satisfying a maximum set of viewpoints. To this end we propose a logical framework based on argumentation and introduce a method of decision making based on backward chaining for the bread industry.

Since a joint argumentation - decision support approach is highly relevant to the food sector (Thomopoulos et al., 2009), the contribution of the paper is twofold. First we present a real use case of an argumentation process in the agrifood domain. Second we introduce the notion of viewpoint / goal in this setting based on the notion of backwards chaining reasoning and show how to use these techniques in a concrete application.
The main alternative method to deal with the problem is the multicriteria decision approach. However, multicriteria decision aims at evaluating several alternative options, whereas argumentation-based decision focuses on whether several options make sense together, which is a different perspective, addressed in this paper. Moreover, multicriteria decision is not connected to the backward chaining procedure as the argumentative approach is, by construction of the arguments, as will be explained in Section 5.2.

In Section 2, we introduce the real scenario considered in the application. In Section 3, we motivate our technical and modeling choices. In Section 4, the developed approach is introduced. It relies on an instantiation of a logic-based argumentation framework based on a specific fragment of first order logic. In Section 5, we explain the technical results that ensure the soundness and completeness of our agronomy application method. In Section 6, some evaluation results are presented. Finally, Section 7 concludes the paper.

2. Scenario

The case of study considered in this paper relates to the debate around the change of ash content in flour used for common French bread. Various actors of the agronomy sector are concerned, in particular the Ministry for Health through its recommendations within the framework of the PNNS (“National Program for Nutrition and Health”), the millers, the bakers, the nutritionists and the consumers.

The PNNS recommends to privilege the whole-grain cereal products and in particular to pass to a common bread of T80 type, i.e. made with flour containing an ash content (mineral matter rate) of 0.8%, instead of the type
T65 (0.65% of mineral matter) currently used. Increasing the ash content comes down to using a more complete flour, since mineral matter is concentrated in the peripheral layers of the wheat grain, as well as a good amount of components of nutritional interest (vitamins, fibers). However, the peripheral layers of the grain are also exposed to the phytosanitary products, which does not make them advisable from a health point of view, unless one uses organic flour.

Other arguments (and of various nature) are in favour or discredit whole-grain bread. From an organoleptic point of view for example, the bread loses out in its “being crusty”. From a nutritional point of view, the argument according to which the fibers are beneficial for health is discussed, some fibers could irritate the digestive system. From an economic point of view, the bakers fear selling less bread, because whole-grain bread increases satiety – which is beneficial from a nutritional point of view, for the regulation of the appetite and the fight against food imbalances and pathologies. However whole-grain bread requires also less flour and more water for its production, thus reducing the cost. The millers also fear a decrease in the quality of the technical methods used in the flour production.

Beyond the polemic on the choice between two alternatives (T65 or T80), one can take the debate further by distinguishing the various points of view concerned, identifying the desirable target characteristics, estimating the means of reaching that point. The contribution of this paper is showing how using argumentation can help towards such practical goals.
3. Motivation

In this paper we will elicit the points of view and the desirable target characteristics by the means of interviews with agronomy experts. Once the target characteristics identified, finding the means of reaching them will be done automatically by a combination of reverse engineering and argumentation. The reverse engineering will be used in order to find the complete set of actions to take towards a given characteristic, for all characteristics. In certain cases the actions to take will be inconsistent. Argumentation will then be employed in order to identify actions that can be accepted together.

3.1. Reverse Engineering

While reverse engineering has been widely employed in other Computer Science domains such as multi agent systems or requirements engineering (e.g., Brunède et al. (2014)), it is quite a novel methodology when applied in agronomy. In agrifood chains, the products traditionally go through the intermediate stages of processing, storage, transport, packaging and reach the consumer (the demand) from the producer (the supply). It is only recently, due to an increase in quality constraints, that the notion of reverse engineering control has emerged (Perrot et al., 2011). In this case the demand (and not the supply) sets the specifications of desired products and it is up to the supply to adapt and find its ways to respond. In what follows, starting from the desired target criteria for the final product, the methods allowing one to identify ways to achieve these criteria (by intervention on the various stages of the supply chain) are named “reverse engineering”.

Reverse engineering is known to be challenging from a methodological
viewpoint. This is due to two main aspects. First, the difficulty of defining
the specifications for the expected finished product. The desired quality cri-
tera are multiple, questionable, and not necessarily compatible. The second
difficulty lies in the fact that the impact of different steps of food process-
ing and their order is not completely known. Some steps are more studied
than others, several successive steps can have opposite effects (or unknown
effects), the target criteria may be outside of the characteristics of products.
Second, reconciling different viewpoints involved in the food sector still raises
unaddressed questions. The problem does not simply consist in addressing
a multi-criteria optimisation problem (Bouysson et al., 2009): the domain
experts would need to be able to justify why a certain decision (or set of
possible decisions) is taken.

3.2. Argumentation

Argumentation is a reasoning model based on the construction and the
evaluation of interacting arguments. It has been applied to nonmonotonic
reasoning, decision making, or for modeling different types of dialogues in-
cluding negotiation. Most of the models developed for these applications are
grounded on the abstract argumentation framework proposed by Dung in
Dung (1995). This framework consists of a set of arguments and a binary
relation on that set, expressing conflicts among arguments. An argument
gives a reason for believing a claim, for doing an action.

Argumentation theory in general (Dung, 1995; Besnard and Hunter, 2008;
Rahwan and Simari, 2009) is actively pursued in the literature. Some ap-
proaches combine argumentation and multi criteria decision making (Am-
goud and Prade, 2009).
Value based Argumentation Frameworks (Bench-Capon, 2003a) have been proposed, where the strength of an argument corresponds to the values it promotes. What we call viewpoint later on in this paper would then correspond to the notion of audience in such setting. Although intuitive, this approach is not adapted in the case of the considered application. Here a value can be “split” into several audiences: there could be contradictory goals even from the same viewpoint. The notion of viewpoint and goals introduced in this setting also remind those proposed by (Assaghir et al., 2011).

3.2.1. Logic-based Argumentation

In this paper we present a methodology combining reverse engineering and logical based argumentation for selecting the actions to take towards the agronomy application at hand. The logical instantiation language is a subset of first order logic denoted in this paper \( \mathcal{SRC} \) equivalent to Datalog+ (Cali et al., 2010), Conceptual Graphs or Description Logics (more precisely the \( \mathcal{EL} \) fragment (Baader et al., 2005) and DL-Lite families (Calvanese et al., 2007)). All above mentioned languages are logically equivalent in terms of representation or reasoning power. The reason why this application is using \( \mathcal{SRC} \) is the graph based representation proper to \( \mathcal{SRC} \) (and not to the other languages). This graph based representation (implemented in the Cogui tool (Chein and Mugnier, 2009; Chein et al., 2013)) makes the language suitable for interacting with non computing experts (Chein et al., 2013).

Here we use the instantiation of (Croitoru and Vesci, 2013) for defining what an argument and an attack are. While other approaches such as (García and Simari, 2004), (Besnard and Hunter, 2005), (Müller and Hunter, 2012) etc. address first order logic based argumentation, the work of (Croitoru and
Vesic, 2013] uses the same $SRG$ syntax and graph reasoning foundations. In Figure 1 the visual interface of Cogui is depicted: knowledge is represented as a graph which is enriched dynamically by rule application. More on the visual appeal of Cogui for knowledge representation and reasoning can be found in (Chein et al., 2013).

4. Approach

As mentioned above, in this paper we use an instantiation of logic based argumentation based on a specific fragment of first order logic. This subset is equivalent to Datalog $+\to$ (Cali et al., 2010), Conceptual Graphs or Description Logics (the $EL$ fragment (Baader et al., 2005) and the DL-Lite families (Calvanese et al., 2007)). The reason for which our application required this...
specific logic fragment is related to the information capitalisation needs of the food sector. The long term aim is to enrich ontologies and data sources based on these ontologies and join the Open Data movement. This entails that the language used by the food applications needs to be compatible with the Semantic Web equivalent languages as mentioned before.

The choice of the SRC syntax and graph reasoning mechanism is justified by the visual appeal of this language for non-computing experts.

In a nutshell our methodology is as follows. The set of goals, viewpoints as well as the knowledge associated with the goals / viewpoints is elicited either by the means of interviews with the domain experts or manually from different scientific papers. This step of the application is the most time consuming but the most important. If the knowledge elicited is not complete, sound or precise the outcome of the system is compromised. Then, based on the knowledge elicited from the knowledge experts and the goals of the experts, we enrich the knowledge bases using reverse engineering (implemented using backwards chaining algorithms). Putting together the enriched knowledge bases obtained by backwards chaining from the different goals will lead to inconsistencies. The argumentation process is used at this step and the extensions yield by the applications computed. Based on the extensions and the associated viewpoints we can use voting functions to determine the application choice of viewpoints.

4.1. Use Case Real Data

Expressing the target characteristics – or goals – according to various points of view consists of identifying the facets involved in the construction of product quality: points of view, topics of concern such as nutrition, envi-
ronment, technology, etc. In addition, such viewpoints have to be addressed according to their various components (fibers, minerals, vitamins, etc). Desirable directions need to be laid down, and in a first step we consider them independent one from another.

The considered sources of information include, from most formal to less formal: (1) peer reviewed scientific papers; (2) technical reports or information posted on websites; (3) conferences and scientific meetings around research projects; (4) expert knowledge obtained through interviews. The scientific articles we have analysed – with the supervision of experts in agrifood – include: (Boure et al., 2008; Slavin and Green, 2007; Dubuisson-Quellier, 2006; Ginon et al., 2009; Layat, 2011). (Boure et al., 2008) compares the different types of flour from a nutritional point of view. (Slavin and Green, 2007) explores the link between fiber and satiety. (Dubuisson-Quellier, 2006; Ginon et al., 2009) deal with consumer behaviour and willingness to pay. They focus on French baguette when information concerning the level of fibers is provided, and they base their results on statistical studies of consumer panels. (Layat, 2011) provides a summary of the nutritional aspects of consumption of bread and the link with technological aspects.

We also reviewed technical reports available on official websites on health policy: the public PNNS (National Program for Nutrition and Health, www.mangerbourger.fr/pnns) (PNNS (documents statutaires), 2010), the European project Healthgrain (looking at improving nutrition and health through grains) (Dean et al., 2007; HEALTHGRAIN, 2009), as well as projects and symposia on sanitary measures regarding the nutritional, technological and organoleptic properties of breads (DINABIO, 2008; CADINNO, 2008; AQUA-
NUP, 2009; FCN, 2009). Finally, several interviews were conducted to collect
domain expert knowledge, in particular for technology specialists in our lab-
ory.

A summary of the results obtained in the baking industry is synthesised in
Figure 2 regarding nutritional and organdptic aspects. Figure 2(a) shows
the main identified goals to reach for a nutritionally optimised bread (for
instance, containing a high level of soluble fibers, vitamins and minerals, low
salt, etc.), whereas Figure 2(b) sums up the main goals to achieve for an
enjoyable bread regarding sensorial concerns (for example, crusty, etc.).

5. Technical Soundness

In this section we explain the technical results that ensure the soundness
and completeness of our agronomy application method. The section is com-
posed of three parts. A first subsection explains the logical subset of first
order logic language employed in the paper. The second subsection shows
how to construct arguments and attacks in order to obtain extensions when
a knowledge base expressed under this language is inconsistent. Last, the
third section shows how we used reverse engineering to complete the knowl-
edge base with all possible actions and how argumentation can be used in
order to select consistent subsets of knowledge which support given actions.

5.1. The Logical Language

In the following, we give the general setting knowledge representation
language used throughout the paper.

A knowledge base is a 3-tuple $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ composed of three finite
sets of formulae: a set $\mathcal{F}$ of facts, a set $\mathcal{R}$ of rules and a set $\mathcal{N}$ of constraints.
Figure 2: Nutritional (a) and organoleptic (b) goals
Let us formally define what we accept as $\mathcal{F}$, $\mathcal{R}$ and $\mathcal{N}$.

**Facts Syntax.** Let $C$ be a set of constants and $\mathcal{P} = P_1 \cup P_2 \ldots \cup P_n$ a set of predicates of the corresponding arity $i = 1, \ldots, n$. Let $\mathcal{V}$ be a countably infinite set of variables. We define the set of terms by $T = \mathcal{V} \cup C$. As usual, given $i \in \{1, \ldots, n\}$, $p \in P_i$ and $t_1, \ldots, t_i \in T$ we call $p(t_1, \ldots, t_i)$ an atom. A fact is the existential closure of an atom or an existential closure of a conjunction of atoms. (Note that there is no negation or disjunction in the facts and that we consider a generalised notion of facts that can contain several atoms.)

- *Bread, Cereal, LowSalt, ContaminantFree* are examples of unary predicates (arity 1) and *IngredientOf* is a binary predicate (arity 2).
  - *Wheat, oats, rye, barley* are constant examples.
  - *Cereal (wheat)* is an atom.
- $\exists x \ (\text{Bread}(x) \land \text{IngredientOf(wheat, x)})$ is a fact.

Due to lack of space we do not show the full semantic definitions of facts (or rules and constraints in the following section). For a complete semantic depiction of this language please check (Chein and Mugnier, 2009; Chein et al., 2013; Croitoru and Vesic, 2013). It is well known that $F' \models F$ (read the fact $F'$ entails the fact $F$) if and only if there is a homomorphism from $F$ to $F'$ (Chein and Mugnier, 2009).

**Rules.** A rule $R$ is a formula of the form
\[
\forall x_1, \ldots, \forall x_n \ \forall y_1, \ldots, \forall y_m \ (H(x_1, \ldots, x_n, y_1, \ldots, y_m) \rightarrow \exists z_1, \ldots, \exists z_k \ C(y_1, \ldots, y_m, z_1, \ldots, z_k))
\]
where $H$, the hypothesis, and $C$, the conclusion, are atoms or conjunctions of atoms, $n, m, k \in \{0, 1, \ldots\}$, $x_1, \ldots, x_n$ are the variables appearing in $H$. 

\[\]
\[\]
\[\]
\[ y_1, \ldots, y_m \text{ are the variables appearing in both } H \text{ and } C \text{ and } z_1, \ldots, z_k \text{ the new variables introduced in the conclusion. An example of a rule is the following:} \\
\forall x \ (\text{Bread}(x) \land \text{PesticideFree}(x) \land \text{MycotoxinFree}(x)) \\
\rightarrow \text{ContaminantFree}(x)). \]

In the following we will consider rules without new existential variables in the conclusion.

Reasoning consists of applying rules on the set \( F \) and thus inferring new knowledge. A rule \( R = (H, C) \) is applicable to set \( F \) if and only if there exists \( F' \subseteq F \) such that there is a homomorphism \( \sigma \) from the hypothesis of \( R \) to the conjunction of elements of \( F' \). A rule \( R = (H, C) \) is inversely applicable to a fact \( F \) if there is a homomorphism \( \pi \) from \( C \) to \( F \). In this case, the inverse application of \( R \) to \( F \) according to \( \pi \) produces a new fact \( F' \) such that \( R(F') = F \). We then say that the new fact is an immediate inverse derivation of \( F \) by \( R \), abusively denoted \( R^{-1}(F) \).

Note that this technique is commonly used, for example, for backward chaining query answering (Baget and Salvat, 2006; Konig et al., 2012) where a query is rewritten according to the rules. The same mechanism is also discussed by abductive reasoning algorithms (Klarman et al., 2011) where minimal sets of facts (in the set inclusion sense) are added to the knowledge base in order to be able to deduce a query.

Let \( F = \text{Bread}(\text{bleuette}) \land \text{PesticideFree}(\text{bleuette}) \land \text{MycotoxinFree}(\text{bleuette}) \) and \( R \) the rule \( \forall x \ (\text{Bread}(x) \land \text{PesticideFree}(x) \land \text{MycotoxinFree}(x) \rightarrow \text{ContaminantFree}(x)) \).

\( R \) is applicable to \( F \) and produces by derivation the following fact: \( \text{Bread}(\text{bleuette}) \land \text{PesticideFree}(\text{bleuette}) \land \text{MycotoxinFree}(\text{bleuette}) \land \text{Contaminant-} \)
Free(bleuette).

Let $F = Bread(bleuette) \land Contaminant\text{Free}(bleuette)$ and $R$ the rule $\forall x \ (Bread(x) \land Pesticide\text{Free}(x) \land Mycotoxin\text{Free}(x) \rightarrow \text{Contaminant\text{Free}}(x))$.

$R$ inversely applicable to $F$ and produces by inverse derivation the fact: $F' = Bread(bleuette) \land Pesticide\text{Free}(bleuette) \land Mycotoxin\text{Free}(bleuette)$.

Let $F$ be a subset of $\mathcal{F}$ and let $\mathcal{R}$ be a set of rules. A set $F_n$ is called an $\mathcal{R}$-derivation of $F$ if there is a sequence of sets (called a derivation sequence) $(F_0, F_1, \ldots, F_n)$ such that $F_0 \subseteq F$, $F_0$ is $\mathcal{R}$-consistent, for every $i \in \{1, \ldots, n-1\}$, it holds that $F_i$ is an immediate derivation of $F_{i-1}$.

Given a set $\{F_0, \ldots, F_k\} \subseteq \mathcal{F}$ and a set of rules $\mathcal{R}$, the closure of $\{F_0, \ldots, F_k\}$ w.r.t. $\mathcal{R}$, denoted $\mathcal{C}_\mathcal{R}(\{F_0, \ldots, F_k\})$, is defined as the smallest set (with respect to $\subseteq$) which contains $\{F_0, \ldots, F_k\}$, and is closed for $\mathcal{R}$-derivation (that is, for every $\mathcal{R}$-derivation $F_n$ of $\{F_0, \ldots, F_k\}$, we have $F_n \subseteq \mathcal{C}_\mathcal{R}(\{F_0, \ldots, F_k\})$). Finally, we say that a set $\mathcal{F}$ and a set of rules $\mathcal{R}$ entail a fact $G$ (and we write $\mathcal{F}, \mathcal{R} \models G$) iff the closure of the facts by all the rules entails $F$ (i.e. if $\mathcal{C}_\mathcal{R}(\mathcal{F}) \models G$).

**Constraints.** A constraint is a formula $\forall x_1 \ldots \forall x_n \ (H(x_1, \ldots, x_n) \rightarrow \bot)$, where $H$ is an atom or a conjunction of atoms and $n \in \{0, 1, 2, \ldots\}$. Equivalently, a constraint can be written as $\neg(\exists x_1, \ldots, \exists x_n \ H(x_1, \ldots, x_n))$. As an example of a constraint, consider $N = \neg(\exists x \ (\text{Growth}(x) \land \text{Decrease}(x)))$.

Given a knowledge base $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$, a set $\{F_1, \ldots, F_k\} \subseteq \mathcal{F}$ is said to be inconsistent if and only if there exists a constraint $N \in \mathcal{N}$ such that $\{F_1, \ldots, F_k\} \models H_N$, where $H_N$ denotes the existential closure of the hypothesis of $N$. A set is consistent if and only if it is not inconsistent. A set $\{F_1, \ldots, F_k\} \subseteq \mathcal{F}$ is $\mathcal{R}$-inconsistent if and only if there exists a constraint...
$N \in \mathcal{N}$ such that $\text{CL}_\mathcal{R} (\{F_1, \ldots, F_k\}) = H_N$, where $H_N$ denotes the existential closure of the hypothesis of $N$.

Let $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ where:

- $\mathcal{F}$ contains the following facts:
  - $F_1 = \text{Bread(bleuette)} \land \text{ContaminantFree(bleuette)}$
  - $F_2 = \exists e \text{ ExtractionRate(e, bleuette)}$
  - $F_3 = \exists f (\text{FiberContent(f, bleuette)} \land \text{High(f)})$

- $\mathcal{R}$ consists of the following rules:
  - $R_1 = \forall x, y (\text{Bread(x)} \land \text{ExtractionRate(y,x)} \land \text{PesticideFree(x)}$
    $\rightarrow \text{Decrease(y)})$
  - $R_2 = \forall x, y, z (\text{Bread(x)} \land \text{ExtractionRate(y,x)} \land \text{FiberContent(z,x)} \land$
    \hspace{1cm} $\text{High(z)} \rightarrow \text{Growth(y)})$
  - $R_3 = \forall x (\text{Bread(x)} \land \text{ContaminantFree(x)}$
    $\rightarrow \text{PesticideFree(x)} \land \text{MycotarinFree(x)})$

- $\mathcal{N}$ contains the following negative constraint:
  - $N = \neg (\exists x (\text{Growth(x)} \land \text{Decrease(x)}))$

$\mathcal{K}$ is inconsistent since $(\mathcal{F}, \mathcal{R}) \models N$. Indeed, $F_1$ and $R_3$ allow to deduce $\text{PesticideFree(bleuette)}$. Combined to $F_2$ and $R_1$ we obtain $\text{Decrease(e)}$. $F_3$ and $R_2$ deduce $\text{Growth(e)}$, violating the negative constraint $N$.

Given a knowledge base, one can ask a conjunctive query in order to know whether something holds or not. Without loss of generality we consider
boolean conjunctive queries (which are facts). As an example of a query, take
\( \exists x_1 \text{cat}(x_1) \). The answer to query \( \alpha \) is positive if and only if \( \mathcal{F}, \mathcal{R} \models \alpha \).

Answering \( Q \), traditionally, has two different algorithmic approaches: either forward chaining or backwards chaining. The two approaches come to either (1) finding an answer of \( Q \) in the \( R \)-derivations of the facts in the knowledge base or (2) computing the inverse \( R \)-derivations of the query and finding if there is a match in the facts. We will focus on the latter approach in the following.

5.2. Arguments and Attacks

This section shows that it is possible to define an instantiation of Dung’s abstract argumentation theory (Dung, 1995) that can be used to reason with an inconsistent ontological KB.

We first define the notion of an argument. For a set of formulae \( \mathcal{G} = \{ G_1, \ldots, G_n \} \), notation \( \bigwedge G \) is used as an abbreviation for \( G_1 \land \ldots \land G_n \).

**Definition 1.** Given a knowledge base \( \mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N}) \), an argument \( a \) is a tuple \( a = (F_0, F_1, \ldots, F_n) \) where:

- \( (F_0, \ldots, F_{n-1}) \) is a derivation sequence with respect to \( \mathcal{K} \)

- \( F_n \) is an atom, a conjunction of atoms, the existential closure of an atom or the existential closure of a conjunction of atoms such that \( F_{n-1} \models F_n \).

This definition, following the definition of (Croitoru and Vesic, 2013) is a straightforward way to define an argument, since an argument corresponds to a derivation.
To simplify the notation, from now on, we suppose that we are given a fixed knowledge base \( K = (\mathcal{F}, \mathcal{R}, \mathcal{N}) \) and do not explicitly mention \( \mathcal{F}, \mathcal{R} \) nor \( \mathcal{N} \) if not necessary. Let \( a = (F_0, \ldots, F_n) \) be an argument. Then, we denote \( \text{Supp}(a) = F_0 \) and \( \text{Conc}(a) = F_n \).

Arguments may attack each other, which is captured by a binary attack relation \( \text{Att} \subseteq \text{Arg}(\mathcal{F}) \times \text{Arg}(\mathcal{F}) \).

**Definition 2.** Let \( K = (\mathcal{F}, \mathcal{R}, \mathcal{N}) \) be a knowledge base and let \( a \) and \( b \) be two arguments. The argument \( a \) attacks argument \( b \), denoted \( (a, b) \in \text{Att} \), if and only if there exists \( \varphi \in \text{Supp}(b) \) such that the set \( \{ \text{Conc}(a), \varphi \} \) is \( \mathcal{R} \)-inconsistent.

This attack relation is not symmetric. To see why, consider the following example. Let \( \mathcal{F} = \{ p(m), q(m), r(m) \}, \mathcal{R} = \emptyset, \mathcal{N} = \{ \forall x_1 (p(x_1) \land q(x_1) \land r(x_1) \rightarrow \perp) \} \). Let \( a = ((p(m), q(m)), p(m) \land q(m)), b = (\{ r(m) \}, r(m)) \). We have \( (a, b) \in \text{Att} \) and \( (b, a) \notin \text{Att} \). This will ensure that the naive extension is different, at least in theory, from the preferred, stable, etc. semantics. However, in our application they all entail the same information as shown later on.

**Definition 3.** Given a knowledge base \( K = (\mathcal{F}, \mathcal{R}, \mathcal{N}) \), the corresponding argumentation framework \( \mathcal{AF}_K \) is a pair \( (A = \text{Arg}(\mathcal{F}), \text{Att}) \) where \( \text{Arg}(\mathcal{F}) \) is the set of all arguments that can be constructed from \( \mathcal{F} \) and \( \text{Att} \) is the corresponding attack relation as specified in Definition 2.

Let \( \mathcal{E} \subseteq A \) and \( a \in A \). We say that \( \mathcal{E} \) is conflict free iff there exists no arguments \( a, b \in \mathcal{E} \) such that \( (a, b) \in \text{Att} \). \( \mathcal{E} \) defends a iff for every argument \( b \in A \), if we have \( (b, a) \in \text{Att} \) then there exists \( c \in \mathcal{E} \) such that \( (c, b) \in \text{Att} \).
\( \mathcal{E} \) is admissible iff it is conflict free and defends all its arguments. \( \mathcal{E} \) is a complete extension iff \( \mathcal{E} \) is an admissible set which contains all the arguments it defends. \( \mathcal{E} \) is a preferred extension iff it is maximal (with respect to set inclusion) admissible set. \( \mathcal{E} \) is a stable extension iff it is conflict-free and for all \( a \in A \setminus \mathcal{E} \), there exists an argument \( b \in \mathcal{E} \) such that \( (b, a) \in \text{Att} \).

\( \mathcal{E} \) is a grounded extension iff \( \mathcal{E} \) is a minimal (for set inclusion) complete extension.

For an argumentation framework \( AS = (A, \text{Att}) \) we denote by \( \text{Ext}_x(AS) \) (or by \( \text{Ext}_x(A, \text{Att}) \)) the set of its extensions with respect to semantics \( x \). We use the abbreviations \( c, p, s, \) and \( g \) for respectively complete, preferred, stable and grounded semantics.

An argument is sceptically accepted if it is in all extensions, credulously accepted if it is in at least one extension and rejected if it is not in any extension.

Based on this definition of arguments and attacks in (Croitoru and Vesic, 2013) was also shown that the rationality postulates of (Caminada and Amgoud, 2007) are respected. This instantiation respects the direct, indirect consistency as well as the closure.

5.3. Formalising the use case

In this subsection we formalise the notions presented in section 4.

Let \( K = (\mathcal{F}, \mathcal{R}, \mathcal{N}) \) be a consistent knowledge base. This is the knowledge base that all actors share and agree upon. In this paper we assume that the rules and negative constraints are common to everybody.

The goals of the different actors can be seen as a set of existentially closed conjuncts. We denote them by \( G_1, G_2, \ldots, G_n \).
Let $G_i$ be a goal and $\mathcal{K}$ the knowledge base. $\mathcal{K}$ is consistent and $\mathcal{K}$ does not entail $G_i$. We compute the inverse $R$-derivations of $G_i$ (where $R$ is the set of rules of the knowledge base). We add all of the $R^{-1}(G_i)$ to the facts. We thus obtain a new knowledge base $\mathcal{K}_i$ which differs from $\mathcal{K}$ solely by its facts set (which now also includes $R^{-1}(G_i)$): $\mathcal{K} = (F \cup R^{-1}(G_i), R, N)$. We also impose that $\mathcal{K}_i$ is consistent.

Given $\mathcal{G} = \{G_1, G_2, ..., G_n\}$, the goals correspond to a set of viewpoints $\mathcal{V}$ (there exists a function $\kappa : \mathcal{G} \rightarrow 2^\mathcal{V}$). This function can assign a goal to one or more viewpoints and each viewpoint can be associated with one or more goals. Given a goal $G_i$, the (set of) viewpoint(s) associated with this goal is denoted by $\kappa(G_i)$. Similarly, given a viewpoint $v_i$, the set of goals associated with it is denoted by $\kappa^{-1}(v_i)$.

**Example 1.** Let the set of viewpoints $\mathcal{V} = \{\text{nutrition, sanitary, organoleptic}\}$ and $\mathcal{G}$ consisting of the following goals: $G_1 = \exists x \ (\text{Bread}(x) \land \text{LowSalt}(x))$, $G_2 = \exists x \ (\text{Bread}(x) \land \text{ContaminantFree}(x))$, $G_3 = \exists x \ (\text{Bread}(x) \land \text{Crusty}(x))$, $G_4 = \exists x \ (\text{Bread}(x) \land \text{TraceElementRich}(x))$.

We have $\kappa(G_1) = \kappa(G_4) = \text{nutrition}$, $\kappa(G_2) = \text{sanitary}$ and $\kappa(G_3) = \text{organoleptic}$. Conversely $\kappa^{-1}(\text{nutrition}) = \{G_1, G_4\}$, $\kappa^{-1}(\text{sanitary}) = \{G_2\}$ and $\kappa^{-1}(\text{organoleptic}) = \{G_3\}$.

The rules will correspond to the set of sufficient conditions needed for the goal $G_i$. In the context of our practical application this is illustrated in Figure 3 (with respect to nutrition goals).

**Example 2.** To reach the goal $G_1 = \exists x \ (\text{Bread}(x) \land \text{LowSalt}(x))$, the
knowledge base $\mathcal{K}$ contains the following rule: $\forall x, y \ (\text{Bread}(x) \land \text{SaltAdjunction}(y, x) \land \text{Decrease}(y) \rightarrow \text{LowSalt}(x))$

Let us now consider the set of goals $\mathcal{G} = \{G_1, G_2, \ldots, G_n\}$ and the initial knowledge base $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$. As described above we compute the $n$ knowledge bases, corresponding to each goal: $\mathcal{K}_i = (\mathcal{F} \cup \mathcal{R}^{-1}(G_i), \mathcal{R}, \mathcal{N})$ for each $i = 1, \ldots, n$. We consider the union of all these knowledge bases:

$$\mathcal{K}_{\text{agg}} = (\mathcal{F} \bigcup_{i=1,\ldots,n} \mathcal{R}^{-1}(G_i), \mathcal{R}, \mathcal{N})$$

**Example 3.** Let $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$ where:

- $\mathcal{F} = \{F_1\} = \{\text{CurrentExtractionRate(T65)}\}$

- $\mathcal{R}$ contains the following rules:
- $R_1 = \forall x, y \ (\text{Bread}(x) \land \text{ExtractionRate}(y, x) \land \text{Decrease}(y)) \\
\quad \rightarrow \text{Digestible}(x))$
- $R_2 = \forall x, z \ (\text{Bread}(x) \land \text{SaltAdjunction}(z, x) \land \text{Decrease}(z) \\
\quad \rightarrow \text{LowSalt}(x))$
- $R_3 = \forall x, y \ (\text{Bread}(x) \land \text{ExtractionRate}(y, x) \land \text{Growth}(y) \\
\quad \rightarrow \text{TraceElementRich}(x))$
- $R_4 = \forall x, y \ (\text{Bread}(x) \land \text{ExtractionRate}(y, x) \land \text{Decrease}(y) \\
\quad \rightarrow \text{PesticideFree}(x))$

\bullet N \text{ contains the following negative constraint:}
- $N = \neg(\exists x \ (\text{Growth}(x) \land \text{Decrease}(x)))$

Let the goal set $\mathcal{G}$ as follows:
- $G_1 = \exists p \ (\text{Bread}(p) \land \text{Digestible}(p))$, where $\kappa(G_1) = \text{nutrition}$
- $G_2 = \exists p \ (\text{Bread}(p) \land \text{LowSalt}(p))$, where $\kappa(G_2) = \text{nutrition}$
- $G_3 = \exists p \ (\text{Bread}(p) \land \text{TraceElementRich}(p))$, where $\kappa(G_3) = \text{nutrition}$
- $G_4 = \exists p \ (\text{Bread}(p) \land \text{PesticideFree}(p))$, where $\kappa(G_4) = \text{sanitary}$.

Then:
- $\mathcal{K}_1 = (\mathcal{F}_1, \mathcal{R}, N)$ where $\mathcal{F}_1 = \mathcal{F} \cup R^{-1}(G_1)$ contains the following facts:
  - $F_1 = \text{CurrentExtractionRate}(T65)$
  - $F_2 = \text{Bread}(p) \land \text{ExtractionRate}(\tau, p) \land \text{Decrease}(\tau)$
- $\mathcal{K}_2 = (\mathcal{F}_2, \mathcal{R}, N)$ where $\mathcal{F}_2 = \mathcal{F} \cup R^{-1}(G_2)$ contains the following facts:
  - $F_1 = \text{CurrentExtractionRate}(T65)$
  - $F_2 = \text{Bread}(p) \land \text{SaltAdjunction}(s, p) \land \text{Decrease}(s)$
- $\mathcal{K}_3 = (\mathcal{F}_3, \mathcal{R}, N)$ where $\mathcal{F}_3 = \mathcal{F} \cup R^{-1}(G_3)$ contains the following facts:
- $F_1 = \text{CurrentExtractionRate}(T_{65})$
- $F_4 = \text{Bread}(p) \land \text{ExtractionRate}(\tau, p) \land \text{Growth}(\tau)$

• $K_4 = (\mathcal{F}_4, R, \mathcal{N})$ where $\mathcal{F}_4 = \mathcal{F} \cup R^{-1}(G_4)$ contains the following facts:
  - $F_1 = \text{CurrentExtractionRate}(T_{65})$
  - $F_2 = \text{Bread}(p) \land \text{ExtractionRate}(\tau, p) \land \text{Decrease}(\tau)$

Finally $K_{agg} = (\mathcal{F} \bigcup_{i=1,\ldots,n} R^{-1}(G_i), R, \mathcal{N})$ where

As observed in the previous example, it may happen that $K_{agg}$ is inconsistent (and it does so even for goals belonging to the same viewpoint). We then use argumentation, which, by the means of extensions will isolate subsets of facts we can accept together (called extensions). Furthermore, the extensions will allow us to see which are the viewpoints associated to each maximal consistent subset of knowledge (by the means of the function $\kappa$). A choice procedure then has to be used (see example below).

The argument framework we can construct from the above knowledge base is $(\mathcal{A}, \text{Att})$ where $\mathcal{A}$ contains the following:

• $a = (\{F_2\}, F_2, R_1(F_2))$ where $R_1(F_2) = \text{Bread}(p) \land \text{ExtractionRate}(\tau, p) \land \text{Decrease}(\tau) \land \text{Edible}(p)$.

• $b = (\{F_3\}, F_3, R_3(F_3))$ where $R_3(F_3) = \text{Bread}(p) \land \text{ExtractionRate}(\tau, p) \land \text{Growth}(\tau) \land \text{TraceElementRich}(p)$.

• $c = (\{F_2\}, F_2, R_4(F_2))$ where $R_4(F_2) = \text{Bread}(p) \land \text{ExtractionRate}(\tau, p) \land \text{Decrease}(\tau) \land \text{PesticideFree}(p)$.

• $d = (\{F_3\}, F_3, R_2(F_3))$ where $R_2(F_3) = \text{Bread}(p) \land \text{SaltAdjunction}(s, p) \land \text{Decrease}(s) \land \text{LowSalt}(p)$ and

$\text{Att} = \{(a, b), (b, a), (b, c), (c, b)\}$. 

23
In this argumentation system defined we now obtain:

- $\text{Ext}_{\text{stable}}(A, \text{Att}) = \text{Ext}_{\text{semi-stable}}(A, \text{Att}) = \text{Ext}_{\text{preferred}}(A, \text{Att}) = \{\{a, c, d\}, \{b, d\}\}$.

Starting from the extensions $\text{Ext}_{\varepsilon}(A, \text{Att})$, the proposed decision support system functions as follows: for every extension $\varepsilon \in \text{Ext}_{\varepsilon}(A, \text{Att})$:

- Consider the facts occurring in the arguments of $\varepsilon$;
- Identify the knowledge bases $\mathcal{K}_i$ where these facts occur;
- Obtain the goals $G_i$ which are satisfied by the extension;
- Using the $\kappa$ function to obtain the viewpoints corresponding to these goals;
- Show domain experts the set of goals, and compatible viewpoints corresponding to the given extension.

This method allows us to obtain a set of options equal to the cardinality of $\text{Ext}_{\varepsilon}(A, \text{Att})$. For taking a final decision several possibilities can be considered and presented to the experts:

- Maximise the number of goals satisfied;
- Maximise the number of viewpoints satisfied;
- Use preference relations of experts on goals and/or viewpoints.

In the previous example (please recall that the goals $G_1$ and $G_2$ are associated with the nutritional viewpoint while $G_4$ is associated with the sanitary viewpoint) we have:
• The first extension \( \{a, c, d\} \) is based on the facts \( F_2 \) and \( F_3 \) obtained from \( K_3 \), \( K_2 \) and \( K_4 \) that satisfy the goals \( G_1 \), \( G_2 \) and \( G_4 \).

• The second extension \( \{b, d\} \) is based on \( F_3 \) and \( F_4 \) obtained from \( K_2 \) and \( K_3 \) satisfying \( G_2 \) and \( G_3 \) both associated with the nutritional viewpoint.

One first possibility (corresponding to the extension \( \{a, c, d\} \)) consists of accomplishing \( F_2 \) and \( F_3 \) and allows to satisfy the biggest number of goals and viewpoints.

The second possibility (corresponding to the extension \( \{b, d\} \)) consists of accomplishing \( F_3 \) and \( F_4 \). It would satisfy two goals and one viewpoint. It could be considered though if the goal \( G_3 \) (not satisfied by the first option) is preferred to the others.

6. Evaluation

The evaluation of the implemented system was done via a series of interviews with domain experts. The above knowledge and reasoning procedures were implemented using the Cogui knowledge representation tool (Chein et al., 2013), with an extension of 2000 lines of supplemental code. Three experts have validated our approach: two researchers in food science and cereal technologies of the French national institute of agronomic research, specialists respectively of the grain-to-flour transformation process and of the breadmaking process, and one industrial expert - the Director of the French National Institute of Bread and Pastry.

The first meeting dealt with the delimitation of the project objectives and addressed fundamental questions such as: Is it possible to uniquely define a
“good” bread? Which scenarios of “good bread” should be considered? How could they be defined from a nutritional, sanitary, sensorial and economic point of view? Which are the main known ways to achieve them?

Then a series of individual interviews constituted the elicitation phase. Each expert gave more arguments which were complementing one each other. In parallel, the writing of specifications for the demonstrator and the definition of the knowledge base structure were conducted.

In the following plenary meeting the real potential of the approach was shown. The experts were formulating goals and viewpoints they were interested in and the Cogni system together with the argumentation extension was yielding the associated possible propositions. Figure 6 shows a screenshot of the demonstrator answers for a two-goal query: a nutritional goal (high fiber content) and an organoleptic goal (crusty bread). Two sets of compatible actions are proposed, some choices (such as increasing or decreasing the extraction rate) being incompatible for both goals, and thus separated in the two alternative sets.

Four scenarios were more specifically evaluated. These scenarios concern four kinds of consumers: obeses (fiber preference), people with iron deficiency (micronutrient preference), people with cardiovascular disease (decreased salt preference) and vegetarians (limited phytic acid), which produces different sets of goals. For each scenario, the system proposes several outputted recommendations. The audience for decreasing salt tips the balance in favour of a recommendation for the T80 bread, while the audience for decreasing phytic acid pushes to specify recommendations towards a natural sourdough bread or a conservative T65 bread. Other audiences are in favor of a status
Figure 4: Demonstrator screenshot showing two sets of possible actions

quo. The results were considered as explainable by experts, but not obvious, since many considerations had to be taken into account.

Two interests of the approach were more particularly highlighted. They concern cognitive considerations. Firstly, experts were conscious that the elicitation procedure was done according to their thought processes, that is, in a forward way which is more natural and intuitive. The system was thus able to restitute the knowledge in a different manner than the experts usually do. Secondly, from a problem that could initially seem simple, the experts realized that it covered a huge complexity that a human mind could hardly address alone. The tool is currently available to them under restricted access.

The knowledge modeling task can be a very time-consuming step. As presented in Section 4.1, several sources of information were used, from peer reviewed scientific papers and technical reports, to conference meetings and expert interviews. On the one hand, expert interviews appeared to be the
least expensive ones in terms of time. A one-day period allows both eliciting knowledge through an interview and formalizing it in the software system — which constitutes the longest part of the work. However, this relatively short time hides a strong prerequisite: having already a clear view of the case study, a synopsis of the questions to ask the expert and an implemented knowledge model. On the other hand, websites, technical reports and scientific articles are more costly to analyze. For instance, the critical reading a scientific paper of the domain may require a one-day period on its own, for a discerning reader. However they allow one to to grasp the ins and outs of the question.

During the evaluation step, the experts raised the question of the importance attached to the different pieces of knowledge modeled in the system. Moreover, in some cases experts may hesitate on the relevance of some facts or rules. A possibility would thus be to adopt a preference-based argumentation system, as proposed in several works such as (Amgoud and Cayrol, 2002; Bench-Capon, 2003b; Kaci and van der Torre, 2008; Amgoud et al., 2000; Bourguet et al., 2013a), able to take into account different levels of importance among arguments.

7. Conclusion

Even if argumentation based decision making methods applied to the food industry were also proposed by (Bourguet, 2010; Bourguet et al., 2013b), this paper addresses a key point in the context of current techniques used by the food sector and namely addressing reverse engineering. Also, in this approach, an argument is used here as a method computing compatible objectives in the sector. This case study represents an original application and
an introspective approach in the agronomy field by providing an argumentation based decision-support system for the various food sectors. It requires nevertheless the very expensive task of knowledge modeling. Such task, in its current state cannot be automated. It strongly depends on the quality of expert opinion and elicitation (exhaustiveness, certainty, etc). The current trend for decision-making tools includes more and more methods of argumentation as means of including experts in the task of modeling and the decision-making processes. Another element to take into account, not discussed in this paper, is the difficulty of technologically (from an agronomy viewpoint) putting in place the facts of each option. Modeling this aspect in the formalism is still to be studied.

Assaghir, Z., Napoli, A., Kaytoue, M., Dubois, D., Prade, H., 2011. Numeri-

applied to food quality in a public health policy. Expert Systems with Applications 40 (11), 4539–4546.

Query Failure Explanation in Inconsistent Knowledge Bases Using Argumentation

Abdallah ARIOUA a, Nouredine TAMANI b, Madalina CROITORU b, and Patrice BUCHE a

a IATE, INRA, University of Montpellier 2
b LIRMM, INRIA, University of Montpellier 2

Abstract.
We address the problem of explaining Boolean Conjunctive Query (BCQ) failure in the presence of inconsistency within the Ontology-Based Data Access (OBDA) setting, where inconsistency is handled by the intersection of closed repairs semantics (ICR) and the ontology is represented by Datalog+/- rules. Our proposal relies on an interactive and argumentative approach where the processes of explanation take the form of a dialogue between the User and the Reasoner. We exploit the equivalence between argumentation and ICR-semantics to prove that the Reasoner can always provide an answer for user’s questions.

1. Introduction

In the popular ONTOLOGY-BASED DATA ACCESS setting the domain knowledge is represented by an ontology facilitating query answering over existing data [15]. In practical systems involving large amounts of data and multiple data sources, data inconsistency with respect to the ontology is unavoidable. Many inconsistency-tolerant semantics [5,2,12,13] have been proposed that rely on the notion of data repairs i.e. subsets of maximally consistent data with respect to the ontology. Query answering under these semantics may not be intuitively straightforward and can lead to loss of user’s trust, satisfaction and may affect the system’s usability [14]. As argued by Calvanese et al. [6] explanation facilities should not just account for user’s “Why Q?” question (why a query holds under a given inconsistency-tolerant semantics) but also for question like “Why not Q?” (why a query does not hold under a given inconsistency-tolerant semantics).

The research problem addressed by this paper is the boolean conjunctive query failure explanation in inconsistent knowledge bases, precisely: “Given an inconsistent KB and a boolean conjunctive query Q, why Q is not entailed from KB under the ICR-semantics?”. We use argumentation as an approach for explanation. We consider the logical instantiation of Dung’s [10] abstract argumentation framework for OBDA in [8] and we exploit the equivalence result shown by the authors between the ICR-semantics and sceptical acceptance under preferred semantics to guarantee the existence of an explanation for any failed query. The explanation takes the form of a dialogue between the User and the Reasoner with the purpose of explaining the query failure. At each level of the dialogue, we use language-based introduced primitives such as clarification and...
deeper to further refine the answer. The added value of our contribution lies in its significance and originality. We are the first to propose query failure explanation in the context of OBDA for inconsistent knowledge bases by means of argumentation. Our approach differs from [4,6] in handling query failure since we consider an inconsistent setting within OBDA. In addition, the work presented in [11] is neither applied to an OBDA context nor to the Datalog+/− language.

2. Background and Overview

In this section, we introduce the motivation and the context of our work and a formal definition of the addressed problem. Consider a knowledge base about university staff and students which contains inconsistent knowledge. This inconsistency is handled by ICR-semantics. The User might be interested in knowing why the knowledge base does not entail the query \( Q \)：“Luca is a student”. Observe that the individual \( \delta \) (e.g. Luca in the example above) is a negative answer for a conjunctive query \( Q \) (e.g. get me all the students in the example above) if and only if the boolean conjunctive query \( Q(\delta) \) (e.g. student(Luca) in the example above) has failed. Hence, in this paper we concentrate only explaining the failure of a boolean conjunctive query. Let us formally introduce the problem of Query Failure Explanation in inconsistent knowledge bases.

Definition 1 (Query Failure Explanation Problem \( \mathcal{P} \)) Let \( \mathcal{K} \) be an inconsistent knowledge base, \( Q \) a Boolean Conjunctive Query such that \( \mathcal{K} \not\models_{ICR} Q \). We then call \( \mathcal{P} = \langle \mathcal{K}, Q \rangle \) a Query Failure Explanation Problem (QFEP).

To address the Query Failure Explanation Problem, we use a logical instantiation of Dung’s [10] abstract argumentation framework for OBDA in [8] ensuring that the argumentation framework used respects the rationality postulates [7].

Let us first introduce the OBDA setting and inconsistency-tolerant semantics. We consider the positive existential conjunctive fragment of first-order logic, denoted by FOL(\( \land, \exists \)), which is composed of formulas built with the connectors (\( \land, \rightarrow \)) and the quantifiers (\( \exists, \forall \)). For more details about the language please check [8]. In this paper, for lack of space we simply give an example of a knowledge base \( \mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N}) \) is composed of finite set of facts \( \mathcal{F} \) and finite set of existential rules \( \mathcal{R} \) and a finite set of negative constrains \( \mathcal{N} \).

Example 1 Let us consider an example inspired from [5]. In an enterprise, employees work in departments and use offices which are located in departments, some employees direct departments, and supervise other employees. In addition, a supervised employee cannot be a manager. A director of a given department cannot be supervised by an employee of the same department, and two employees cannot direct the same department, and an employee cannot work in more than one department. The following sets of (existential) rules \( \mathcal{R} \) and negative constraints \( \mathcal{N} \) model the corresponding ontology:

\[
\mathcal{R} = \begin{cases}
\forall x \forall y \left( \text{works\_in}(x,y) \rightarrow \text{emp}(x) \right) & \text{(r1)} \\
\forall x \forall y \left( \text{directs}(x,y) \rightarrow \text{emp}(x) \right) & \text{(r2)} \\
\forall x \forall y \left( \text{directs}(x,y) \land \text{works\_in}(x,y) \rightarrow \text{manager}(x) \right) & \text{(r3)} \\
\forall x \forall y \forall z \left( \text{locate\_office}(y,z) \land \text{uses\_office}(x,y) \rightarrow \text{works\_in}(x,z) \right) & \text{(r4)}
\end{cases}
\]
works_in uses_office works their closure. The following is of the repairs:
different semantics can be used for query answering over the knowledge base. In this
works conflicting (because she works also for the department of Accounting).

\[ N = \begin{cases} 
\forall x \forall y (\text{supervises}(x, y) \land \text{manages}(y)) \rightarrow \bot & (n_1) \\
\forall x \forall y (\text{supervises}(x, y) \land \text{works_in}(x, z) \land \text{directs}(y, z)) \rightarrow \bot & (n_2) \\
\forall x \forall y (\text{works_in}(x, y) \land \text{works_in}(x, z)) \rightarrow \bot & (n_3)
\end{cases} \]

Let us suppose the following set of facts \( F \) that represent explicit knowledge:
- \( \text{directs}(\text{John}, d_1) \)
- \( \text{directs}(\text{Tom}, d_2) \)
- \( \text{supervises}(\text{Tom}, \text{John}) \)
- \( \text{works_in}(\text{John}, d_1) \)
- \( \text{works_in}(\text{Tom}, d_2) \)
- \( \text{works_in}(\text{Carlo}, \text{Statistics}) \)
- \( \text{works_in}(\text{Luca}, \text{Statistics}) \)
- \( \text{uses_office}(\text{Linda}, o_1) \)
- \( \text{locate_office}(o_1, \text{Accounting}) \)

Let \( F \subseteq \mathcal{F} \) be a set of facts and \( \mathcal{R} \) be a set of rules. An \( \mathcal{R} \)-derivation of \( F \) in \( \mathcal{X} \) is a
finite sequence \( \{F_0, \ldots, F_n\} \) of sets of facts such that \( F_0 = F \), and for all \( i \in \{0, \ldots, n\} \) there is a
rule \( r_i = (H_i, C_i) \in \mathcal{R} \) and a logical entailment from the \( H_i \) to \( F_i \). For a set of facts \( F \subseteq \mathcal{F} \)
and a query \( Q \) and a set of rules \( \mathcal{R} \), we say \( F, \mathcal{R} \models Q \) if there exists an \( \mathcal{R} \)-derivation
\( \{F_0, \ldots, F_n\} \) such that \( F_n \models Q \). Given a set of facts \( F \subseteq \mathcal{F} \) and a set of rules \( \mathcal{R} \), the closure
of \( F \) with respect to \( \mathcal{R} \), denoted by \( \text{Cl}_\mathcal{R}(F) \) is the minimal set of all the knowledge that can be derived from a set of facts \( F \) by applying all the rules of \( \mathcal{R} \). Finally, we say that
a set of facts \( F \subseteq \mathcal{F} \) and a set of rules \( \mathcal{R} \) entail a fact \( f \) (and we write \( F, \mathcal{R} \models f \)) if the
closure of \( F \) by all the rules entails \( f \) (i.e. \( \text{Cl}_\mathcal{R}(F) \models f \)).

Given a knowledge base \( \mathcal{X} = (\mathcal{F}, \mathcal{R}, \mathcal{N}) \), a set \( F \subseteq \mathcal{F} \) is said to be inconsistent
iff there exists a constraint \( n \in \mathcal{N} \) such that \( F \models H_n \), where \( H_n \) is the hypothesis of the
constraint \( n \). A set of facts is consistent iff it is not inconsistent. Notice that (like in
classical logic) one can entail everything from an inconsistent set. A common solution [2, 12]
is to construct maximal (with respect to set inclusion) consistent subsets of \( \mathcal{X} \). Such
subsets are called repairs and denoted by \( \text{Repair}(\mathcal{X}) \). Once the repairs are computed,
different semantics can be used for query answering over the knowledge base. In this
paper we focus on (Intersection of Closed Repairs semantics) [2] and we will denote
ICR entailment as \( \mathcal{X} \models_{\text{ICR}} Q \).

Example 2 The knowledge base in Example 1 is inconsistent because the set of facts
\( \{f_1, f_2, f_3\} \subseteq \mathcal{F} \) is inconsistent since it violates the negative constraint \( n_2 \). To be able to
reason in presence of inconsistency one has to construct first the repairs and intersect
their closure. The following is of the repairs:
- \( \mathcal{R}_1 = (\text{directs}(\text{John}, d_1), \text{supervises}(\text{Tom}, \text{John}), \text{works_in}(\text{Linda}, \text{Statistics}), \text{works_in}(\text{Jane}, \text{Statistics}), \text{emp}(\text{Tom}), \text{emp}(\text{Carlo}), \text{emp}(\text{Linda})) \)

The intersection of all closed repairs is:
\[ \bigcap_{\mathcal{R} \equiv \text{Repair}(\mathcal{X})} \text{Cl}_\mathcal{R}(A) = \{\text{directs}(\text{Tom}, d_2), \text{works_in}(\text{Carlo}, \text{Statistics}), \text{works_in}(\text{Luca}, \text{Statistics}), \text{works_in}(\text{Jane}, \text{Statistics}), \text{emp}(\text{Carlo}), \text{emp}(\text{Jane}), \text{emp}(\text{Luca}), \text{emp}(\text{Tom}), \text{emp}(\text{Linda})\} \]
3. Argumentation Framework, Deepening and Clarification

In what follows we quickly recall the definition of argumentation framework in the context of rule-based languages. We use the definition of argument of [8] and extend it to the notions of deepened and clarified arguments. Given a knowledge base $\mathcal{K} = (\mathcal{F}, \mathcal{R}, \mathcal{N})$, the corresponding argumentation framework of $\mathcal{K}$ is a pair $(\mathcal{Arg}, \mathcal{Att})$ where $\mathcal{Arg}$ is the set of arguments that can be constructed from $\mathcal{F}$ and $\mathcal{Att}$ is an asymmetric binary relation called attack defined over $\mathcal{Arg} \times \mathcal{Arg}$. Given an argument $a$ we denote by $\text{Supp}(a)$ the support of the argument and by $\text{Conc}(a)$ the conclusion.

Example 3 (Argument) The following argument indicates that John is an employee because he directs department $d_1$:

$$ a = (\{\text{directs}(John, d_1)\}, \{\text{directs}(John, d_1), \text{emp}(John)\}, \text{emp}(John)). $$

Example 4 (Attack) Consider the argument $a$ of Example 3, the following argument $b = (\{\text{supervises}(Tom, John), \text{works_in}(Tom, d_1)\}, \{\text{supervises}(Tom, John) \land \text{works_in}(Tom, d_1)\}, \text{directs}(John, d_1))$ attacks $a$, because $\{\text{supervises}(Tom, John) \land \text{works_in}(Tom, d_1)\}$ is $\mathcal{R}$-inconsistent since it violates the constraint $n_2$.

The results of [8] show the equivalence between sceptically acceptance under preferred semantics and ICR-entailment. Let us now propose functionalities that give the User the possibility to manipulate arguments to gain clarity for query answering and namely: deepening and clarification. Deepening aims at showing the reason why an argument attacks another. In our knowledge base the attack is justified by the violation of a constraint. Put differently, an argument attacks another argument if the conclusion of the former and the hypothesis of the latter are mutually exclusive. Thus deepening amounts to explain the attack between two arguments by showing the violated constraint.

**Definition 2 (Deepening)** Given two arguments $a, b \in \mathcal{A}$. The mapping deepening denoted by $\mathcal{D}$ is a total function from the set $\mathcal{Att}$ to $2^\mathcal{A}$ defined as follows: $\mathcal{D}(b, a) = \{n_i \in \mathcal{N} \land \exists f \in \text{Supp}(a) \text{ such that } \text{Cl}_f(\text{Conc}(b), f) \models H_n \}$

Note that $H_n$ is the hypothesis of the constraint $n$. 

Example 5 (Deepening) Consider the argument $a$ of Example 3, the argument $b = (\{\text{supervises}(Tom, John), \text{works_in}(Tom, d_1)\}, \{\text{supervises}(Tom, John) \land \text{works_in}(Tom, d_1)\}, \text{directs}(John, d_1))$ attacks $a$, hence deepening is $\mathcal{D}(b, a) = \{\forall x \forall z (\text{supervises}(x, y) \land \text{work_in}(x, z) \land \text{directs}(y, z)) \rightarrow \bot\}$. This explains why the argument $b$ attacks $a$.

The information carried by the argument would be more useful if the structure exhibits the line of reasoning leading to the conclusion, called clarifying the argument.

**Definition 3 (Clarifying)** Given an argument $a \in \mathcal{A}$. The mapping clarification denoted by $\mathcal{C}$ is a total function from the set $\mathcal{A}$ to $2^\mathcal{R}$ such that: $\mathcal{C}(a) = (F_0, ..., F_n) = \{r | r \in \mathcal{R} \text{ s.t. } r \text{ is applicable to } F_i \text{ and the application of } r \text{ on } F_i \text{ yields } F_i+1 \text{ for all } i \in \{0, ..., n\}\}$

**Definition 4 (Clarified Argument)** Given an argument $a \in \mathcal{A}$. The corresponding clarified argument $\mathcal{C}_a$ is a 3-tuple $(\text{Supp}(a), \mathcal{C}(a), \text{Conc}(a))$ such that $\mathcal{C}(a) \subseteq \mathcal{R}$ are the rules used to derive the conclusion $\text{Conc}(a)$. 

197
Example 6 (Clarification count. Example 3) A clarified version of the argument \( a \) is \( C_a = \{ \text{\texttt{directs(John,d1)}} \}, \{ \text{\texttt{\forall x\forall d \text{directs(x,d)} \rightarrow emp(x)}} \}, \text{\texttt{emp(John)}} \} \) such that \( \text{Supp}(C_a) = \{ \text{\texttt{\forall x\forall d \text{directs(x,d)} \rightarrow emp(x)}} \} \) and \( \text{\texttt{\text{Conc}(C_a)}} = \text{\texttt{emp(John)}} \).

4. Dialectical Explanation for Query Failure

In what follows, we describe a simple dialectical system of explanation based on the work of [9]. Our system is custom-tailored for the problem of Query Failure Explanation under ICR-semantics in inconsistent knowledge bases with rule-based language. Our dialectical explanation involves two parties: the User and the Reasoner. The User wants to understand why the query is not ICR-entailed and the Reasoner provides a respond aiming at showing the reason why the query is not ICR entailed. We model this explanation through a dialogue composed of moves (speech acts) put forward by both the User and the Reasoner. This dialogue is governed by rules (pre/post conditions rules, termination rules, success rules) that specify what type of moves should follow the other, the conditions under which the dialogue terminates, and when and under which conditions the explanation has been successfully achieved (success rules).

We denote by \( \text{Arg}^+ (Q) \) the set of all arguments that support the query \( Q \), namely \( a \in \text{Arg}^+ (Q) \) iff \( \text{\texttt{\text{Conc}(a)}} \models Q \). In what follows we define types of moves that can be used in the dialogue.

**Definition 5 (Moves)** A move is a 3-tuple \( m = \langle ID, I, \omega \rangle \) such that:

1. \( m \) is an explanation request, denoted by \( m^{\text{ERQ}} \) iff \( ID = \text{User} \), \( I \) is a query \( Q \) and \( \omega \) is an argument supporting \( Q \).
2. \( m \) is an explanation response, denoted by \( m^{\text{ERP}} \) iff \( ID = \text{Reasoner} \), \( I \) is an argument supporting \( Q \) and \( \omega \) is an argument such that \( \omega \) attacks \( I \).
3. \( m \) is a follow-up question, denoted by \( m^{\text{FQ}} \) iff \( ID = \text{User} \), \( I \) is an argument and \( \omega \) is either \( \text{\texttt{\text{Conc}(I)}} \) or an argument \( \omega_0 \) that supports \( \text{\texttt{Q s.t. (\omega, \omega_0)}} \in \text{\texttt{Att}} \).
4. \( m \) is a follow-up answer, denoted by \( m^{\text{FA}} \) iff \( ID = \text{Reasoner} \), \( I \) is an argument and \( \omega \) is either a deepening \( \text{\texttt{D}} \) or a clarified argument \( \text{\texttt{C(I)}} \).

The explanation request \( m^{\text{ERQ}} = \langle \text{User}, Q, \omega \rangle \) is an explanation request made by the User asking "why the query \( Q \) is not ICR-entailed while there is an argument \( \omega \) asserts the entailment of \( Q \)". An explanation response \( m^{\text{ERP}} = \langle \text{Reasoner}, \omega, \omega_0 \rangle \) made by the Reasoner is an explanation for the previous inquiry by showing that the argument \( \omega \) (that supports \( Q \)) is the subject of an attack made by \( \omega_0 \). The User also can ask a follow-up question if the Reasoner provides an explanation. The follow-up question \( m^{\text{FQ}} = \langle \text{User}, \omega_0, \omega \rangle \) is a compound move, it can represent a need for deepening (the User wants to know why the argument \( \omega_0 \) is attacking the argument \( \omega \)) or the need for clarification (how the argument \( \omega_0 \) comes to a certain conclusion). To distinguish them, the former has \( \omega = \text{\texttt{\text{Conc}(\omega_0)}} \) and the latter has \( \omega \) as an argument. A follow-up answer \( m^{\text{FA}} = \langle \text{Reasoner}, \omega_0, \omega \rangle \) is also a compound move. Actually, it depends on the follow-up question. It shows the argument \( \omega_0 \) that needs to be deepened (resp. clarified) and its deepening (resp. clarification) by the deepening mapping \( \text{\texttt{D(\omega_0, \omega)}} \) (resp. clarification mapping \( \text{\texttt{C(\omega)}} \)) in Definition 4 (resp. Definition 6). An example is provided afterward.
In what follows we specify the structure of dialectical explanation and the rules that have to be respected throughout the dialogue.

**Definition 6 (Dialectical Explanation)** Given a QFEP $\mathcal{P}$, a dialectical explanation $\mathcal{D}_{exp}$ for $\mathcal{P}$ is a non-empty sequence of moves $\langle m_1^s, m_2^s, \ldots, m_n^s \rangle$ where $s \in \{ERQ, FQ, ERP, FA\}$ and $i \in \{1, \ldots, n\}$ such that:

1. The first move is always an explanation request $m_1^s$, we call it an opening.
2. $s \in \{ERQ, FQ\}$ if $i$ is odd, $s \in \{ERP, FA\}$ if $i$ is even.
3. For every explanation request $m_i^{ERQ} = \langle \text{User}, I_i, \omega_i \rangle$, $I_i$ is the query $Q$ to be explained and $\omega_i$ is an argument supporting $Q$ and for all $m_j^{ERQ}$ s.t $j < i$ $\omega_i \neq \omega_j$.
4. For every explanation response $m_i^{ERP} = \langle \text{Reasoner}, I_i, \omega_i \rangle$ s.t $i \geq 1$, $I_i = \omega_{i-1}$ and $\omega_i = \omega' s.t (\omega', I_{i-1}) \in \text{Att}$.
5. For every follow-up question $m_i^{FQ} = \langle \text{User}, I_i, \omega_i \rangle$ s.t $i \geq 1$, $I_i = \omega_{i-1}$ and $\omega_i$ is either $I_{i-1}$ or $\text{Conc}(\omega_{i-1})$.
6. For every follow-up answer $m_i^{FA} = \langle \text{Reasoner}, I_i, \omega_i \rangle$ s.t $i \geq 1$, $I_i = \omega_{i-1}$ and $\omega_i = \text{D}(I_i, \omega_{i-1})$ or $\omega = \text{C}(I_i)$.

We denote by $\text{Arg}_\text{user}(\mathcal{D}_{exp})$ the set of all arguments put by the User in the dialogue.

Every dialogue has to respect certain rules (protocol). These rules organize the way the Reasoner and the User should put the moves. For each move we specify the conditions that have to be met for the move to be valid (preconditions). We also specify the conditions that identify the next moves (postconditions).

**Definition 7 (Pre/Post Condition Rules)** Given a QFEP $\mathcal{P}$ and a dialectical explanation $\mathcal{D}_{exp}$ for $\mathcal{P}$. Then, $\mathcal{D}_{exp}$ has to respect the following rules:

**Explanation request:**
- Preconditions: The beginning of the dialogue or the last move of the Reasoner was either an explanation response or a follow-up answer.
- Postconditions: The next move must be an explanation answer.

**Explanation response:**
- Preconditions: The last move by the User was an explanation request.
- Postconditions: The next move must be either another explanation request (it may implicitly mean that the User had not understood the previous explanation) or a follow-up question.

**Follow-up question:**
- Preconditions: The last move by the Reasoner was an explanation response or this follow-up question is not the second in a row.
- Postconditions: The next move must be a follow-up answer.

**Follow-up answer:**
- Preconditions: The last move by the User was a follow-up question.
- Postconditions: The next move must be an explanation request (it may implicitly mean that the User had not understood the previous explanation).
Beside the previous rules, there are termination rules that indicate the end of a dialectical explanation.

**Definition 8 (Termination Rules)** Given a QFEP $\mathcal{P}$ and a dialectical explanation $\mathcal{D}_{exp}$ for $\mathcal{P}$, then, $\mathcal{D}_{exp}$ terminates when the User puts an empty explanation request $m_{ERQ}^i = \langle \text{User}, 0, 0 \rangle$ or when $\text{Arg}_{\text{User}}(\mathcal{D}_{exp}) = \text{Arg}^+(Q)$.

The rules in Definition 7 & 8 state that the Reasoner is always committed to respond with an explanation response, the User then may indicate the end of the dialogue by an empty explanation request (Definition 8) declaring his/her understanding, otherwise starts another explanation request (this indicates that he/she has not understood the last explanation) or asks a follow-up question, the User cannot ask more than two successive follow-up questions. If the User asks a follow-up question then the Reasoner is committed to a follow-up answer. When the User asks for another explanation he/she cannot use an argument that has already been used. If the User ran out of arguments and he/she has not yet understood, the dialogue ends (Definition 8) and the explanation is judged unsuccessful. It is important to notice that when the Reasoner wants to answer the User there may be more than one argument to chose. There are many “selection strategies” that can be used in such case (for instance, the shortest argument, the least attacked argument...etc), but their study is beyond the scope of the paper.

In what follows we elaborate more on the success and the failure of an explanation.

**Definition 9 (Success Rules)** Given a QFEP $\mathcal{P}$ and a dialectical explanation $\mathcal{D}_{exp}$ for $\mathcal{P}$. Then, $\mathcal{D}_{exp}$ is successful when it terminates with an empty explanation request $m_{ERQ}^i = \langle \text{User}, 0, 0 \rangle$, otherwise it is unsuccessful.

A dialectical explanation is judged to be successful if the User terminates the dialogue voluntarily by putting an empty explanation request. If the User has used all arguments supporting $Q$ then he/she is forced to stop without indicating his/her understanding, in this case we consider the explanation unsuccessful. By virtue of the equivalence between ICR-semantics and argumentation presented in Section 3, the existence of response is always guaranteed. This property is depicted in the following proposition.

**Proposition 1 (Existence of response)** Given a QFEP $\mathcal{P}$ and a dialectical explanation $\mathcal{D}_{exp}$ for $\mathcal{P}$. Then, for every $m_{s}^i \in \mathcal{D}_{exp}$ s.t $s \in \{\text{ERQ}, \text{FQ}\}$ and $1 \leq i \leq |\mathcal{D}_{exp}|$, the next move $m_{s+1}^i$ s.t $s \in \{\text{ERP}, \text{FA}\}$ always exists.

5. Conclusion

In this paper, we have presented a dialectical approach for explaining boolean conjunctive queries failure, designated by Query Failure Explanation Problem (QFEP), in an inconsistent ontological knowledge base where inconsistency is handled by inconsistency-tolerant semantics (ICR) and issued from the set of facts. The introduced approach relies on both (i) the relation between ontological knowledge base and logical argumentation framework and (ii) the notions of argument deepening and clarifications. So, through a dialogue, the proposed approach explains to the User how and why his/her query is not entailed under ICR semantics.
We currently investigate the explanation problem not only for Query Failure but also for Query Answering. We have proposed a Query Explanation framework under the CoGui editor\cite{1} and plan to test the two approaches within the DUR-DUR ANR project which investigates the use of argumentation in agri-food chains.

Abstract. In the aim of evaluating and improving link quality in bibliographical knowledge bases, we develop a decision support system based on partitioning semantics. The novelty of our approach consists in using symbolic values criteria for partitioning and suitable partitioning semantics. In this paper we evaluate and compare the above mentioned semantics on a real qualitative sample. This sample is issued from the catalogue of French university libraries (SUDOC), a bibliographical knowledge base maintained by the University Bibliographic Agency (ABES).

1 Introduction

Real World Context. The SUDOC (catalogue du Système Universitaire de Documentation) is a large bibliographical knowledge base managed by ABES (Agence Bibliographique de l’Enseignement Supérieur). The SUDOC contains bibliographic notices (document descriptions \( \approx 10\,000\,000 \)), and authorship notices (person descriptions \( \approx 2\,000\,000 \)). An authorship notice possesses some attributes (ppn\(^1\), appellation set, date of birth...). A bibliographic notice also possesses some attributes (title, ppn\(^2\), language, publication date...) and link(s) to authorship notices. A link is labeled by a role (as author, illustrator or thesis advisor) and means that the person described by the authorship notice has participated as the labeled role to the document described by the bibliographic notice.

One of the most important tasks for ABES experts is to reference a new book in SUDOC. To this end, the expert has to register the title, number of pages, types of publication domains, language, publication date, and so on, in a new bibliographic notice. This new bibliographic notice represents the physical books in the librarian hands which he/she is registering. He/she also has to register people which participated to the book’s creation (namely the contributors). In order to do that, for each contributor, he/she selects every authorship notice (named candidates) which has an appellation similar to the book contributor. Unfortunately, there is not that much information in authorship notices because the librarian politics is to give minimal information, solely in order to distinguish two authorship notices which have the same appellation, and nothing more (they reference books, not people!). So the librarian has to look at bibliographic notices which are linked to authorship notices candidates (the bibliography of candidates) in

\(^1\) A ppn identifies a notice.
order to see whether the book in his/her hands seems to be a part of the bibliography of a particular candidate. If it is the case, he/she links the new bibliographic notice to this candidate and looks at the next unlinked contributor. If there is no good candidate, he/she creates a new authorship notice to represent the contributor.

This task is fastidious because it is possible to have a lot of candidates for a single contributor (as much as 27 for a contributor named "BERNARD, Alain"). This creates errors, which in turn can create new errors since linking is an incremental process. In order to help experts to repair erroneous links, we proposed two partitioning semantics in [11] which enables us to detect erroneous links in bibliographic knowledge bases. A partitioning semantics evaluates and compares partitions.

Contribution. The contribution of this paper is to practically evaluate the results quality of partitioning semantics [11] on a real SUDOC sample. We recall the semantics in section 3, clearly explain on which objects and with which criteria the semantics have been applied in section 2, and present qualitative results in section 4. We discuss the results and conclude the paper in section 5.

2 Qualitative experiments

In this section, we first adapt the entity resolution problem [4] to investigate link quality in SUDOC in section 2.1. This problem is known in literature under very different names (as record linkage [16], data deduplication [2], reference reconciliation [14]...). Then we define (section 2.3) and detail (section 2.4) criteria used in order to detect erroneous links in SUDOC. Those criteria are used on SUDOC subsets defined in section 2.2.

2.1 Contextual entities: from erroneous links to entity resolution

In order to detect and repair erroneous links, we represent SUDOC links into contextual entity (the i contextual entity is denoted $N_{c_i}$). A contextual entity represents a bibliographic notice $N_{b_i}$ from the viewpoint of one of its contributor, named the C contributor of $N_{c_i}$ and denoted $C(N_{c_i})$. The contextual entities are compared together with an entity resolution method, in order to see which ones have a contributor representing a same real-word person. As explained in [8], traditional entity resolution methods cannot be directly applied. This entity resolution method is supposed to group (in a same class of the created partition) the contextual entities such as their C contributor represents a same real-word person, and to separate the other ones (to put them in distinct partition classes). A contextual entity $N_{c_i}$ has several attributes. Most of them are $N_{b_i}(N_{c_i})$ attributes (as title, publication date, publication language, publication domain codes list) and others depend on the C contributor:

\[ A \text{ partition } P \text{ of an object set } X \text{ is a set of classes } (X \text{ subsets}) \text{ such as each object of } X \text{ is in one and only one } P \text{ class.} \]

\[ \text{The entity resolution problem is the problem of identifying as equivalent two objects representing the same real-world entity.} \]
– role of the C contributor (there is a set of typed roles as “thesis_advisor”),
– list of the possible appellations of the C contributor. An appellation is composed of
a name and a surname, sometimes abbreviated (as “J.” for surname),
– list of contributors which are not C. For each of them, we have the identifier of the
authorship notice which represents it, and the role.

The publication language attribute is typed (for example, “eng” for English lan-
guage, “fre” for French language and so on). The publication date is most of the time
the publication year (“1984”). Sometimes information is missing and it only gives the
century or decade (“19XX” means that the document has been published last century).
A publication domain is not a describing string but a code with 3 digits which represent
a domain area.

Example 1 (Contextual entity attributes). The authorship notice of ppp 026788861,
which represents “CHRISTIE, Agatha” is linked as “author” to the bibliographic no-
tice of ppp 121495094, which represents “Evil under the sun” book. The contextual
entity which represents this links has the following attributes:

– title: “Evil under the sun”
– publication date: “2001”
– publication language: “eng”
– publication domain codes list: {} (they have not been given by a librarian)
– list of the possible appellations of the C contributor: {“CHRISTIE, Agatha”, “WEST-
MACOTT, Mary”, “MALLOWAN, Agatha”, “MILLER, Agathe Marie Clarissa”}
– role of the C contributor: “author”
– list of contributors which are not C: {} (there is no other contributors in this case)

Let $N_{ci}$ be the contextual entity identified by $i$. As any contextual entity, it has been
constructed because of a link between an authorship notice and a bibliographic notice,
which are respectively denoted $Na(N_{ci})$ and $Nb(N_{ci})$. We define two particular par-
titions: the initial one and the human one.

The initial partition (denoted $P_i$) of contextual entities is the one such as two
contextual entities $N_{ci}, N_{cj}$ are in a same class if and only if $Na(N_{ci}) = Na(N_{cj})$.
This represents the original organization of links in SUDOC.

The human partition (denoted $P_h$) of contextual entities is a partition based on an
human expert’s advice: two contextual entities $N_{ci}, N_{cj}$ are in a same class if and only
if the expert thinks that their C contributor corresponds to a same real word person.

The goal of this paper’s work is to distinguish SUDOC subsets constructed as in the
following section 2.2 with or without erroneous links. We make the hypothesis that the
human partition has to be a best one (because it is the good one according to expert) and
that the initial partition has to not be a best partition except if $P_i = P_h$. So, partitioning
semantics are approved if $P_h$ is a best partition according to the semantics, but not $P_i$.
Let us determine what is a SUDOC contextual entities subset to partition.

2.2 Selecting contextual entities on appellation

A SUDOC subset $S$ selected for an appellation $A$ contains all contextual entities which
represent a link between any SUDOC bibliographic notice and a SUDOC authorship
notice which has an appellation close to the appellation A. To select a SUDOC subset for a given appellation (as “BERNARD, Alain”) is a way to separate SUDOC in subsets which can be treated separately. This is also a simulation of how experts select a SUDOC subset to work on it, as explained in part 1. In the following, we will only be interested into partitioning SUDOC subsets selected for an appellation. Let us define and describe criteria used in order to compare contextual entities together.

2.3 Symbolic criteria

In the general case, a criterion is a function which compares two objects and returns a comparison value. Let \( c \) be a criterion, and \( o_i, o_j \) are two objects. We denote \( c(o_i, o_j) \), the comparison values according to \( c \) between \( o_i \) and \( o_j \).

In this work case, we use **symbolic criteria** which can return **always**, **never**, **neutral**, a **closeness value** or a **farness value** as comparison value. **always** (respectively **never**) means that objects have to be in a same (respectively distinct) partition class\(^2\). Closeness (respectively farness) values are more or less intense and far from the **neutral** value, meaning that objects should be in a same (respectively distinct) partition class. Closeness (respectively farness) values are strictly ordered between themselves, specific to a criterion and less intense than **always** (respectively **never**). Those values are denoted +, ++ and so on (respectively −, −−) such as the more + (respectively −) symbols they have, the more intense and the further from neutral the value is. For a criterion, **always** is more intense than + + + + +, which is more intense than ++ which is more intense than +. + is only more intense than neutral. neutral means that the criterion has no advice about whether to put objects in a same class or not.

2.4 Criteria for detecting link issues in SUDOC

In order to simulate human expert behaviour, nine symbolic criteria have been developed. Some are closeness-criteria\(^4\) (title, otherContributors), farness-criteria\(^4\) (thesis, thesisAdvisor, date, appellation, language) and others are both (role, domain).

Each of these criteria give the **neutral** comparison value when a required attribute of a compared contextual entity is unknown and by default. Let \( \text{Ne}_i, \text{Ne}_j \) be two contextual entities.

- **appellation** criterion is a particular farness-criterion. Indeed, it compares appellation lists to determine which contextual entities can not have a same contributor C. When it is certain (as when appellations are “CONAN DOYLE, Arthur” and “CHRISTIE, Agatha”), it gives a **never** comparison value, which forbids other criteria to compare the concerned authorship notices together. This is also used to divide SUDOC in subsets which should be evaluated separately.

- **title** criterion is a closeness-criterion. This criterion can give an **always** value and 3 closeness comparison values. It is based on a Levenshtein comparison [13]. It is useful to determine which contextual entities represent a same work, edited several times. This is used by the **thesis** criterion.

\(^4\) A closeness-criterion (respectively a farness-criterion) \( c \) is a criterion which can give a closeness or **always** (respectively a farness or **never**) comparison value to two objects.
otherContributors criterion is a closeness-criterion. It counts the others contributors in common, by comparing their authorship notices. One (respectively several) other common contributor gives a + (respectively ++) comparison value.

thesis criterion is a farness-criterion. \( \text{thesis}(N_{c_i}, N_{c_j}) = - \) means that \( N_{c_i}, N_{c_j} \) are contextual entities which represent distinct thesis (recognized thanks to the title criterion) from their "author" point of view. \( \text{thesis}(N_{c_i}, N_{c_j}) = -- \) means that \( N_{c_i}, N_{c_j} \) have also been submitted simultaneously.

thesisAdvisor criterion is a farness-criterion. \( \text{thesisAdvisor}(N_{c_i}, N_{c_j}) = -- \) (respectively \( - \)) means that \( N_{c_i}, N_{c_j} \) have a same contributor C if and only if this contributor has supervised a thesis before (respectively two years after) submitting his/her own thesis.

date criterion is a farness-criterion. For 100 (respectively 60) years at least between publication dates, it gives a -- (respectively -) comparison value.

language criterion is a farness-criterion. When publication languages are distinct and none of them is English, language returns a -- value.

role criterion returns + when contributor C roles are the same (except for current roles as “author”, “publishing editor” or “collaborator”), or -- when they are distinct (except for some pairs of roles as “thesis advisor” and “author”).

domain criterion compares list of domain codes. Domain codes are pair-wise compared. \( \text{domain}(N_{c_i}, N_{c_j}) \) gives closeness (respectively farness) comparison values if every \( N_{c_i} \) domain codes is close (respectively far) from a \( N_{c_j} \) domain code and the other way around.

Let us resume global and local semantics before to evaluate their relevance with respect to the above mentioned criteria on real SUDOC subsets.

3 Partitioning semantics

Let us summarize partitioning semantics detailed in [11]. A partitioning semantics evaluates and compares partitions on a same object set. The following partitioning semantics (in sections 3.1 and 3.2) are based on symbolic criteria.

3.1 Global semantics

In this section we define what is a a best partition on the object set \( \mathcal{O} \) (with respect to the \( \mathcal{C} \) criteria set) according to global semantics. A partition has to be valid\(^5\) in order to be a best one. A partition \( P \) has also an \text{intra value} and an \text{inter value} per criterion of \( \mathcal{C} \). The intra value of a criterion \( c \) depends of the most intense (explained in section 2.3) farness or \textit{never} value of \( c \) such as it compares two objects in a same class (should not be the case according to \( o \)). In the same way, the inter value of \( c \) depends of the most intense closeness or \textit{always} value of \( c \) such as it compares two

\(^5\)A partition \( P \) is valid if and only if there is no two objects \( o_i, o_j \) such as: (i) they are in a same class of \( P \) and they \textit{never} have to be together according to a criterion (expressed by \textit{never} comparison value), or (ii) they are in distinct \( P \) classes but \textit{always} have to be together according to at least a criterion.
objects in distinct $P$ classes. The inter value measures proximity between classes and the intra value measures distance between objects in a class [10]. We note that the neutral comparison value does not influence partition values.

A partition $P$ on an object set $\mathcal{O}$ is a best partition according to a criteria set $\mathcal{C}$ if $P$ is valid and $P$ has a best value, meaning that it is impossible to improve an inter or intra value of any criterion $C \in \mathcal{C}$ without decreasing inter or intra value of a criterion $C' \in \mathcal{C}$ (it is a Pareto equilibrium [15]).

Table 1. Example of objects set

Example 2 (Global semantics evaluating a partition on an object set $\mathcal{O}$).

Let us represent an object set $\mathcal{O} = \{\text{Nc}_1, \text{Nc}_2, \text{Nc}_3, \text{Nc}_4, \text{Nc}_5, \text{Nc}_6\}$ in table 1. Each object is a contextual entity and represents a link between a bibliographic notice and an authorship notice (here, an “author” of a book). Id is the object identity. For each of them, title, date of publication, publication domain and appellation of the contributor $\mathcal{C}$ are given as attributes.

$\text{Nc}_1$ and $\text{Nc}_2$ represent a same person, as $\text{Nc}_4$, $\text{Nc}_5$ does. The human partition on $\mathcal{O}$ is: $P_h = \{\{\text{Nc}_1, \text{Nc}_2\}, \{\text{Nc}_3\}, \{\text{Nc}_4, \text{Nc}_5\}, \{\text{Nc}_6\}\}$. This partition, according to global semantics and with respect to the criteria set $\mathcal{C} = \{\text{appellation, title, domain, date}\}$ (criteria are detailed in section 2.4) is not coherent with some of $\mathcal{C}$ criteria. The $P_h$ value is such that:

- inter classes domain value is very bad (always) because $\text{Nc}_1$ and $\text{Nc}_2$ are in distinct classes but are both about religion.
- intra classes date value is bad (−−) because $\text{Nc}_4$ and $\text{Nc}_5$ are in a same class, but with publication dates distant of more than 60 years and less than 100 years.

$P_h$ has a best partition value because increasing an inter or intra criterion value (as inter domain value by merging $\{\text{Nc}_1, \text{Nc}_2\}$ and $\{\text{Nc}_3\}$ classes) is not possible without decreasing an other inter or intra criterion value ($\text{Nc}_2$ and $\text{Nc}_3$ have publication dates distant more than 100 years, so put them in a same class will decrease date intra value).

3.2 Local semantics

The local semantics, when evaluating a partition on an object set $\mathcal{O}$ with respect to a criteria set $\mathcal{C}$, gives a partition value per parts of $\mathcal{O}$. Parts of $\mathcal{O}$ can be coherent or incoherent. An incoherent part $\mathcal{O}_a$ is a subset of $\mathcal{O}$ such as:
– there is no \( c(o_i, o_j) \), an \textit{always} or closeness value with \( Nc_i \in O - O_a; Nc_j \in O_a \), and \( c \in C \);  
– there is no subset of \( O_a \) for which the previous property is true;  
– there is \( b(o_k, o_l) \), a farness or \textit{never} value such as \( o_k, o_l \in O_a \), and \( b \in C \).

An \textit{incoherent part} \textit{partition value} is based on every comparison between objects which are in it. The \textbf{coherent part} of an object set \( O \) is a \( O \) subset containing every \( O \) object which is not in a incoherent part of \( O \). The \textbf{coherent part partition value} of \( O \) is based on every comparison between objects which are not in the same incoherent part of \( O \).

\textbf{Example 3 (Incoherent and coherent parts).}

Let us identify incoherent parts of the object set \( O \) according to \( C \) given in example 2. \( Nc_1, Nc_2, Nc_3 \) are close together due to \textit{domain} criterion: they are about religion. \( Nc_1, Nc_2, Nc_3 \) are not close to \( Nc_4, Nc_5 \) or \( Nc_6 \) according to any of \( C \) criteria and \( Nc_2, Nc_3 \) are far according to \textit{date} criterion \( \text{date}(Nc_2, Nc_3) = -\) so \{ \( Nc_1, Nc_2, Nc_3 \) \} is an incoherent part of \( O \). The same way, \( Nc_4, Nc_5 \) are close together according to \textit{title} and \textit{domain} criteria, but not close to \( Nc_6 \). \( Nc_4, Nc_5 \) are also far according to \textit{date} criterion \( \text{date}(Nc_4, Nc_5) = -\) so \{ \( Nc_4, Nc_5 \) \} is also an incoherent part.  

So, there are 2 incoherent parts in \( O \): \{ \( Nc_1, Nc_2, Nc_3 \) \} and \{ \( Nc_4, Nc_5 \) \}. \( Nc_6 \) is not in an incoherent part so \( Nc_6 \) is in the coherent part of \( O \).

A partition on \( O \) is a \textbf{best partition according to local semantics} if it has best partition values for each incoherent part of \( O \) and for the \( O \) coherent part.

\textbf{Example 4 (Local semantics evaluating a partition on an object sets \( O \)).}

In example 3, we identified the incoherent parts of the object set \( O = \{ Nc_1, Nc_2, Nc_3, Nc_4, Nc_5, Nc_6 \} \) according to the criteria set \( C = \{ \text{appellation}, \text{title}, \text{domain}, \text{date} \} \).

The partition on \( O \) given in example 2: is \( Ph = \{ \{ Nc_1, Nc_2 \}, \{ Nc_3 \}, \{ Nc_4, Nc_5 \}, \{ Nc_6 \} \} \). According to local semantics, \( Ph \) has 3 values, one for the coherent part and 2 for incoherent parts (1 per incoherent part):

\begin{itemize}
  \item a perfect value for the coherent part of \( O \);  
  \item the incoherent part \{ \( Nc_1, Nc_2, Nc_3 \) \} has a very bad int value for the \textit{domain}  
    criterion (\textit{always});  
  \item the incoherent part \{ \( Nc_4, Nc_5 \) \} has an bad intra value for the \textit{date} criterion (\textit{--});
\end{itemize}

This semantics enables us to split an object set into several parts which can be evaluated separately. We explained local and global semantics in this part, which are a way to solve the entity resolution problem. Let us evaluate them on a real SUDOC sample.

4 Results

ABES experts have selected 537 contextual entity divided into 7 SUDOC subsets selected for an appellation. The table 2 shows for each SUDOC subset selected for an appellation A (please see section 2.2):
1. \(|N_c|\) is the number of contextual entities which represent a link between a bibliographic notice and an authorship notice which has a close appellation to \(A\).
2. \(|N_a|\) is the number of authorities notices according to human partitions (corresponding to class number of human partition).
3. “\(Ph\) best” (respectively “\(Pi\) best”) shows whether the human partition \(Ph\) (respectively initial partition \(Pi\)) has a best value according to global semantics and with respect to all 9 criteria detailed in part 2.4.
4. \(Ph \succ Pi\) is true if and only if \(Ph\) has a better value than \(Pi\).

| Appellation         | \(|N_c|\) | \(|N_a|\) | \(Ph\) best | \(Pi\) best | \(Ph \succ Pi\) | \(Ph\)’ best | Repairs |
|---------------------|----------|----------|-------------|-------------|-----------------|-------------|---------|
| “BERNARD, Alain”    | 185      | 27       | no          | not valid   | yes             | yes         | 1       |
| “DUBOIS, Olivier”   | 27       | 8        | no          | no          | yes             | no          | 1       |
| “LEROUX, Alain”     | 59       | 6        | no          | not valid   | yes             | yes         |         |
| “ROY, Michel”       | 52       | 9        | yes         | not valid   | yes             | yes         |         |
| “NICOLAS, Maurice”  | 20       | 3        | yes         | no          | yes             | yes         |         |
| “SIMON, Alain”      | 63       | 13       | no          | no          | yes             | no          | 1       |
| “SIMON, Daniel”     | 151      | 16       | no          | not valid   | yes             | yes         |         |

**Table 2.** Human and initial partitions with respect to 9 criteria and global semantics

**Local semantics.** has the same results than global semantics on this sample.

For global semantics, \(Pi\) is never a best partition. 5 times out of 7, \(Ph\) does not have a best value (each time, it is due to the domain and language criteria, and two times thesisAdvisor is also involved), but it is all the time valid and better than \(Pi\), which is encouraging for erroneous link detection. Erroneous links are particularly obvious when \(Pi\) is not even valid (4 times out of 7). It is due to the title criterion detailed in part 2.4. We regret that \(Ph\) is not all the time a best partition, but the global semantics is able to distinguish \(Pi\) from \(Ph\) in 5 cases out of 7: when \(Pi\) is not valid, or when \(Ph\) is a best partition but not \(Pi\).

Because the domain and language criteria often considers that \(Ph\) is not a good enough partition, \(Ph\) was also evaluated for global semantics according to all criteria without domain and language (shown in table 2 in column “\(Ph\)’ best”) and that increases the human partition which obtains a best value in 3 more cases (for “BERNARD, Alain”, “SIMON, Daniel” and “LEROUX, Alain” appellations). This tells us that domain and language criteria are not reasonably accurate.

**In order to evaluate if Ph is far from having a best partition value.** we enumerate the number of repairs to transform \(Ph\) into a partition \(Ph''\) which has a best value according to all criteria except domain and language. We show this repair number in the “Repairs” column of table 2. An atomic repair could be:

- merging two partition classes (corresponds to merging two contextual entities which represent a same real word person), or
splitting a partition class in two classes (corresponds to separate books which are attributed to a same real word person but belong to two distinct real word persons).

We can see that only a few repairs are needed compared to the number of classes (corresponding to \( |Na| \) column in the table): 1 repair for “DUBOIS, Olivier” and for “BERNARD, Alain” appellations.

Let us highlight that observing human partition values has permitted to detect and correct an erroneous link (for “ROY, Michel” appellation) in the human reference set, validated with experts. The global semantics does not always consider that the human partition is a best partition, but in the worst case the human partition is very close to be one according to repairs number, and global semantics allow us to detect that initial partitions are much worse than human partitions. This last point is encouraging. This means that the semantics can also be useful to help in criteria tuning, by showing which criteria are bad according to human partitions, and for which authorship notices comparison. For example, the fact that the human partition value is often bad according to the domain criterion shows that this criterion is actually not an accurate criterion. Let us talk about other entity resolution methods and conclude.

5 Discussion

The entity resolution problem \([4][16][14][6]\) is the problem of identifying as equivalent two objects representing the same real-world entity. The causes of such mismatch can be due to homonyms (as in people with the same name), errors that occurred at data entry (like “Léa Guizo” for “Léa Guizol”), missing attributes (e.g. publication date = XXXX), abbreviations (“L. Guizol”) or attributes having different values for two objects representing the same entity (change of address).

The entity resolution problem can be addressed as a rule based pairwise comparison rule approach. Approaches have been proposed in literature \([12]\) using a training pairs set for learning such rules. Rules can be then be chained using different constraints: transitivity \([3]\), exclusivity \([12]\) and functional dependencies \([1]\) \([9]\).

An alternative method for entity resolution problem is partitioning (hierarchical partitioning \([5]\), closest neighbor-based method \([7]\) or correlation clustering \([3]\)). Our work falls in this last category. Due to the nature of treating criteria values, the closest approach to our semantics are \([3]\) and \([2]\). We distinguish ourself to \([3]\) and \([2]\) because of (1) the lack of neutral values in these approaches, (2) the numerization of symbolic values (numerically aggregated into \(-1\) and \(+1\) values), and (3) the use of numerical aggregation methods on these values.

Conclusion. In this paper we proposed a practical evaluation of the global and local semantics proposed in \([11]\). The conclusions of this evaluation are:

- For SUDOC subsets selected by appellation, both semantics are effective to distinguish a human partition from the initial partition; however it is not perfect with respect to our set of criteria (if the human partition is not a best partition, it has a close value).
- Both semantics could be useful to detect meaningless criteria.
As immediate next steps to complete this our work we mention using global or local semantics to improve implemented criteria.
